The dipeptide *T*-2*a*, His Lys, contains the histidyl residue *C*-terminal in the chymotryptic hæm peptide, since of the three histidyl residues in the protein the other two are in the interior of the hæm peptide in a His Thr sequence and in *C*-XXV*a* or *T*-10*a* in a His Gly sequence The peptide following the chymotryptic hæm peptide must, therefore, have an *N*-terminal lysyl residue Three such peptides were isolated from the chymotryptic digest, *C*-XXV*a*, *C*-XVIII*b* and *C*-XXIII*a* Peptide *C*-XXIII*a*, Lys Lys Ala Thr Asp-NH$_2$ Glu, is the only peptide obtained from the chymotryptic digest that does not have a *C*-terminal residue at which chymotrypsin could hydrolyse a peptide bond and for which it was not possible to show that it is followed in the overall amino-acid sequence by another peptide It was therefore assigned to the *C*-terminal position in the protein (preceding communication by E M and E L S) Similarly, the corresponding *C*-terminal peptide *T*-18, Ala Thr Asp-NH$_2$ Glu, was obtained from the tryptic digest (preceding communication by G K and H T) *C*-XXIII*a* can therefore be eliminated as a possible candidate for continuation of the chymotryptic hæm peptide On the other hand, from the *C*-terminal end of the protein, peptide *C*-XVIII*b* follows the single tryptophan-containing peptide, *C*-XX*a*, because of the series of overlapping unique sections of chymotryptic and tryptic peptides discussed later and thus is located in the second half of the overall amino-acid sequence Hence, *C*-XXV*a*, Lys Thr Gly Pro Asp-NH$_2$ Leu His Gly - Leu Phe, is the only peptide in the chymotryptic digest which can represent the sequence immediately following the chymotryptic hæm peptide This conclusion is supported by the finding that, from a partial chymotryptic digest, a hæm peptide was isolated which contains, in addition to the minimal chymotryptic hæm peptide listed in Table 1 of the preceding communication (by E M and E L S.), also the amino-acid sequence of *C*-XXV*a*

The entire amino-acid sequence of *C*-XXV*a*, except for the *N*-terminal lysyl residue, is present in *T*-10*a*, which also contains a Gly Arg sequence at its *C*-terminal end This Gly Arg sequence is unique in the entire protein and *C*-XXVI*a* possesses Gly Arg at its *N*-terminal end Thus, *T*-10*a* provides a definitive overlap for placing *C*-XXVI*a* immediately after *C*-XXV*a*

The unique composition and the *N*-terminal residue of the first half of peptide *T*-17, Thr(Ala,Glu-NH$_2$,-Gly,Pro)Phe Thr Tyr Thr Asp (Ala,Asp)Lys shows that the *N*-terminal portion of this peptide contains the same sequence as the *C*-terminal part of *C*-XXVI*a*, the complete sequence of which is Gly Arg.Lys Thr - Gly Glu-NH$_2$ Ala Pro Gly Phe. Moreover, the *C*-terminal portion of the sequence of *T*-17 clearly contains the dipeptide *C*-XIII*a*, Thr Tyr, as well as the first five residues of *C*-XX*a*, Thr Asp Ala Asp-NH$_2$ Lys Asp-NH$_2$ Lys Gly.Ileu Thr Try. Hence the derived sequence of chymotryptic peptides is *C*-XXV*a* *C*-XXVI*a* *C*-XIII*a* *C*-XX*a*, and the sequence of tryptic peptides is *T*-2 *T*-10*a*.*T*-3 *T*-17, extending the overall amino-acid sequence to the 59th residue.

Peptide *T*-11*a* includes the *C*-terminal sequence of *C*-XX*a*, as well as a *C*-terminal lysine residue, thus showing that the chymotryptic peptide following *C*-XX*a* is one of the three having an *N*-terminal lysyl residue (*C*-XXV*a*, *C*-XVIII*b* or *C*-XXIII*a*). The same argument applies in this case as for the demonstration of the adjacent positions of the hæm peptide and *C*-XXV*a* already discussed above. Peptide *C*-XXIII*a* cannot follow *C*-XX*a* as it represents the *C*-terminal sequence of the protein. Since the remaining part of the amino-acid sequence of the protein can readily be established from the *C*-terminal end of the overall sequence to peptide *C*-XVIII*b*, *C*-XVIII*b* is the only possible continuation of *C*-XX*a*.

The *N*-terminal half of peptide *T*-19, Glu(Glu,Leu,-Thr)(Glu,Met) Tyr Leu Glu Asp-NH$_2$ Pro Lys, clearly contains the same sequence as *C*-XVIII*b*, Lys Glu - Glu Thr Leu Met Glu Tyr, except for the *N*-terminal lysyl residue. On the other hand, the *C*-terminal portion of *T*-19 contains the sequence of the first five residues of *C*-XXIV*a*, Leu Glu Asp-NH$_2$ Pro - Lys Lys Tyr, showing that *C*-XXIV*a* immediately follows *C*-XVIII*b*.

Since the *C*-terminal sequence of *C*-XXIV*a* is Lys Lys Tyr , the following tryptic peptide must be one having an *N*-terminal tyrosyl residue. Only one such tryptic peptide was found, namely, *T*-11, with the sequence Tyr Ileu(Pro,Gly)Thr Lys. The other three tyrosyl residues in the protein are present in the interior of tryptic peptides *T*-17, *T*-19 and *T*-19*a*, which contain the *C*-terminal tyrosyl residues of *C*-XII*a*, *C*-XVIII*b* and *C*-XXVIII*a*, respectively. The *C*-terminal sequence of *T*-11 is unique and corresponds to the first five residues of *C*-XVIII*a*, Ileu Pro Gly Thr Lys Met. Thus, *C*-XVIII*a* follows *C*-XXIV*a* and the overall sequence is established to the 80th residue.

The *C*-terminal sequence of *C*-XVIII*a* is Lys Met , hence the following tryptic peptide must contain an *N*-terminal methionyl residue. The only such peptide is *T*-12*b*, Met Ileu Phe Ala Gly Ileu Lys. The only other methionyl residue in the protein is present in the interior of *C*-XVIII*b* and *T*-19. Peptide *T*-12*b* contains, in addition to the second methionine in the protein, the dipeptide *C*-XIV*a*, Ileu Phe, and the first four residues of *C*-XXVIII*a*. This unique sequence, Ala Gly Ileu Lys, constitutes the four *C*-terminal residues of *T*-12*b* and the four *N*-terminal residues of the fifteen-residue chymotryptic peptide *C*-XXVIII*a*, Ala Gly Ileu Lys Lys Lys Thr Gly Arg - Glu Asp Leu Ileu Ala Tyr , this demonstrates that *C*-XXVIII*a* follows *C*-XIV*a*, which itself follows *C*-XVIII*a*. It should be noted that *C*-XXVIII*a* contains the sequences of the tryptic peptides *T*-8, *T*-8*a* and *T*-19*a*, so that the correct sequence of the tryptic peptides is *T*11 *T*-12*b* *T*-8*a* T-19*a*.

The six residues at the *N*-terminal portion of the octapeptide *T*-19*a*, Glu Asp Leu Ileu Ala Tyr Leu - Lys , are in the same sequence as the six residues at the *C*-terminal part of peptide *C*-XXVIII*a*, showing that the last two residues of *T*-19*a*, Leu Lys, follow the *C*-terminal tyrosyl residue of *C*-XXVIII*a*, thereby placing leucine (*C*-IV*a*) the only free amino-acid recovered in the chymotryptic digest. The chymotryptic peptide following *C*-IV*a* must contain *N*-terminal lysine and is, therefore, *C*-XXIII*a*, Lys Lys Ala Thr Asp-NH$_2$ Glu, the only chymotryptic peptide with *N*-terminal lysine not yet allocated and which represents the *C*-terminal sequence of the protein. It should be recalled (preceding communications) that cytochrome *c* possesses a *C*-terminal glutamic acid residue. Such a residue would not be expected to be *C*-terminal in peptides derived from chymotryptic or tryptic digests.

Discussion

The amino-acid sequence of horse heart cytochrome *c* given in Fig. 1 accounts for the entire composition and amide distribution of the protein. From this sequence the calculated molecular weight of the protein (Margoliash, E., Hill, R. L., Kimmel, J. R., and Schmidt, W. R., in preparation) is 12,398, corresponding to an iron content of 0.45 per cent. These values agree well with those previously determined from the iron content of the chromatographically purified[2] or the crystalline protein[3], on the basis of a content of one atom of iron per mole of protein.

Horse heart cytochrome *c* does not show any obvious relationship in its amino-acid sequence to either the α- or β-chains of human hæmoglobin *A* (ref. 4) or to that of sperm whale myoglobin (ref. 5), although there are distinct similarities between the two hæmoglobin chains and myoglobin (ref. 6). In horse heart cytochrome *c* the hæm is bonded by thiol ether linkages to residues 14 and 17, a position which is much nearer the *N*-terminal end of the chain than the location of the non-covalently bound hæm of either hæmoglobin or myoglobin[7,8]. This lack of similarity is not unexpected in view of the different functions of cytochrome *c* and the oxygen-carrying hæm proteins.

Some noteworthy features of the amino-acid sequence of cytochrome *c* are as follows:

(1) The *N*-terminal α-amino group is acetylated, a situation which has also been shown to occur in several other cases[9], already cited in the preceding communications. Acylated *N*-terminal residues may be expected to occur in other situations, particularly if one considers that *N*-terminal amino-acids have not been found in a number of other proteins by chemical methods.

(2) Those acidic residues which are not present as amides appear to have some tendency to be found in groups. Thus there are Asp Val Glu, Glu Glu , Glu Tyr Leu Glu and Glu Arg Glu Asp sequences. However, two glutamyl and one aspartyl residues are not in these areas.

(3) On the other hand, the basic amino-acids of cytochrome *c* are mainly grouped in small regions of the protein chain. These residues are shown in italics in Fig. 1. Of the nineteen lysyl, two arginyl and three histidyl residues, there are Lys Gly Lys Lys, Lys Gly - Gly Lys His Lys, Arg Lys, Lys Asp-NH$_2$ Lys, Lys - Lys Lys and two Lys Lys sequences. Only three lysyl, one arginyl and two histidyl residues are not included in these sequences.

(4) There is an even more remarkable grouping of large hydrophobic residues (Leu Ileu,Phe,Tyr,Try)

which are marked in bold-faced letters in Fig 1 The chain includes the following sequences of such residues Ileu Phe, Leu His Gly Leu Phe, Phe Thr Tyr, Ileu Thr Try, Leu Met, Glu Tyr Leu, Tyr Ileu, Ileu.Phe Ala.Gly Ileu, and Leu Ileu Ala - Tyr Leu.

Cytochromes *c* of the mammalian type, defined as those cytochromes *c* that can readily interact with the appropriate enzyme systems of the terminal oxidation chain obtained from mammalian sources, have been isolated from a large variety of organisms These include mammals, birds, fish and plant cells At least twelve of these cytochromes *c* have been crystallized to date All have molecular weights of about 12,000, a basic isoelectric point and an oxidation reduction potential of about + 0 250 V It will be of interest to ascertain whether this similarity of function and physical properties is expressed in amino-acid sequences that show the same striking features as the protein from horse heart A comparison of the amino-acid sequences of cytochromes *c* of the mammalian type should yield a picture of those portions of the pattern which are essential for the formation of the specific native three-dimensional structure that constitutes cytochrome *c*, and of those parts of the amino-acid sequence which can vary within the limits set by the structural requirements of the molecule Thus far, such a comparison has been limited to a study of sequences adjoining the hæm group in certain cytochromes[10]

We wish to acknowledge the aid furnished by grants from the National Institutes of Health, U S Public Health Service (E L S) and the Rockefeller Foundation (H T)

OBITUARIES

Prof. M. W Travers, F.R.S.

MORRIS WILLIAM TRAVERS, emeritus professor of chemistry in the University of Bristol and the senior Fellow (by date of election) of the Royal Society, died on August 25 at the age of eighty-nine

Travers was born into a medical family on January 24, 1872 He was educated at Blundell's School, Tiverton, and University College, London After a period at the University of Nancy, he returned to University College as a demonstrator in 1894, and became assistant professor in 1898 The ten years from 1894 to 1904 were among the most fruitful in Travers's career, for he returned to London in time to play an active part in Ramsay's brilliant work which led to the discovery and examination of the rare gases The excitement of this period lived vividly with Travers during the next sixty years, and he never tired of recalling the steps which led to these discoveries

In 1904, shortly after his election to the Royal Society, Travers was appointed to the chair of chemistry at University College, Bristol He brought with him the hydrogen liquefier which he had just perfected at London, and during his time at Bristol his research was concerned largely with low temperatures His main interests, however, centred on the movement for the foundation of a University of Bristol He wrote a pamphlet on the need for a University and the principles to be observed in its constitution; this pamphlet had wide circulation, and Travers enlisted both local and national support for his proposals His enthusiasm was in no small measure responsible for the movement which culminated in the offer by H O Wills in 1908 of £100,000 towards the endowment of a University, but by this time Travers had left Bristol

In 1907 he became director of the Indian Institute of Science at Bangalore, a post which he held until his return to the United Kingdom in 1914 On the outbreak of war it was soon realized that Great Britain would suffer a serious shortage of chemical glassware, which until then had all been imported from the Continent Travers set to work to devise suitable glasses for chemical use and took his processes to a small glassworks in Walthamstow The enthusiasm with which he had carried through his researches in the laboratory was equally effective in the factory, and very soon 'Duroglass' was in successful production

After the First World War, Travers was concerned with furnace technology, he patented a furnace and for a while ran a factory to produce it In 1922 he was elected president of the Society of Glass Technology He returned to Bristol in 1927 as honorary professor, Fellow and Nash lecturer in chemistry He now resumed academic research and staged a come-back on a topic new to him—the study of gaseous and heterogeneous reactions In this field he brought to bear his superb experimental skill, and was ahead of his time in insisting on a complete and careful analysis of all the products of a reaction His return to academic life culminated in his presidency of the Faraday Society in 1936 He did not, however, sever all links with industry, he became a consultant to the National Smelting Co , Ltd , in 1931, and continued to work in this capacity, apart from a break during 1940–45, either on a full- or part-time basis up to his death In 1937 he retired from the University of Bristol and was accorded the title of emeritus professor

At the start of the Second World War Travers offered his services to the Royal Ordnance Factories, and, as a consultant, threw himself whole-heartedly into the diverse problems which had to be solved He made many contributions, particularly in connexion with the application of silicon iron in sulphuric acid manufacture, and in the development of rocket cordite In his dealings with technological problems he had a remarkable facility for putting his finger on the source of trouble It was amazing to see a man, who was for most of the War more than seventy years of age, travel many miles, usually at night, to face the problems in the widely scattered ordnance factories In this period he was a wonderful example to the younger scientists and technologists in his untiring enthusiasm for work

Soon after the end of the War, Travers moved to Stroud and began what was for him one of his greatest and most congenial tasks, the production of a full biography of Sir William Ramsay This work, which Travers had began in 1937, was taken up again in 1948, and the book was written between Travers's eighty-first and eighty-third birthdays, it is one of the great biographies of our time and it will surely remain as a monument to Sir William Ramsay and a fitting memorial to Travers

Prof Travers is survived by his wife, formerly Miss Dorothy Gray, a pianist of outstanding ability, whom he married in 1909, by their daughter and by their son, who is now professor of educational psychology at the University of Utah

I am indebted to Mr S W G. Morgan, Dr W G Hiscock and Mr J Lumsden, of the Imperial Smelting Corporation, for providing information about Travers's industrial career D H Everett

Prof. R. H Dastur, O.B E.

India has lost a distinguished plant physiologist and agronomist by the death of Prof R H. Dastur, which occurred at Bombay on October 1, 1961, at the age of sixty-five years

Rustom Hormusji Dastur was born on March 7, 1896 After graduating as bachelor of science in 1918 at the Gujarat College, Ahmedabad, he was appointed a demonstrator in botany at the same College and obtained the M Sc degree in botany, by research, in 1921 His association at the Gujarat College with the noted botanist Prof W T Saxton gave young Dastur a good grounding in systematic botany and ecology Dastur's interests, however, turned very early in his career towards plant physiology, despite the fact that he had little regular training in plant physiological research, except perhaps for a year (1924–25) he spent at the University of Reading, England, with Prof W Stiles There he experimentally tested his earlier ideas on the relation of water content to photosynthesis (*Ann Bot*, 38, 779, 1924) and made a new departure by measuring photosynthesis in a leaf attached to the plant (*Ann Bot*, 39, 769; 1925)

Dastur was appointed assistant lecturer in botany at the Royal Institute of Science, Bombay, in 1921, and continued there as professor and head of the Department of Botany during 1929–1935 During this period of about half a decade he established a very active school of plant physiology, and his investigations, in collaboration with his pupils, related to the influence on photosynthesis of factors such as water and chlorophyll content, and quality and polarization of light, physiology and anatomy of tendrils, respiration, and physiology of the rice plant The results of these investigations were published in the *Annals of Botany*, the *Journal of the Indian Botanical Society* and the *Indian Journal of Agricultural Science*.

In the year 1935 Dastur's interest shifted from the academic to the applied side of plant physiology, and work on the cotton crop claimed his entire interest for the next 26 years and constituted the *magnum opus* of his scientific output

In 1919 the crop of the Panjab-American cotton, hitherto the main standby of the cultivator in the canal colonies of the Panjab, suffered a serious setback when it was attacked by a disease called 'tirak' By 1935, another seven failures of the crop, partial or complete, occurred. Various theories were advanced to explain this condition but none satisfactorily accounted for and solved the mystery of the occasional failures of the crop Prof Dastur was then invited by the Indian Central Cotton Committee to undertake investigation into this problem, and it was indeed a far-sighted and bold step on the part of the Committee and Mr H. R (later Sir Herbert) Stewart, the then director of agriculture, Panjab, to pin their faith on one who until he undertook the investigation had no previous contact with or knowledge of the cotton plant This investigation, carried out from 1935 until 1943 and described in several scientific papers and eventually in a monograph, was reviewed in *Nature* (158, 524, 1946) Sir Herbert Stewart summed it up in the words "The story which it unfolds is a striking example of how investigations into the realm of pure science can be turned to practical account in everyday agricultural practice"

Dastur retired from service in 1951 on attaining the age of fifty-five years The Indian Central Cotton Committee, however, retained his services in an honorary capacity until the time of his death for directing and supervising plant physiological and agronomic research schemes on cotton

During 1944–61, Prof Dastur was engaged in investigations on (1) causes of bad opening of bolls in Sind, (2) causes of the low yield of sea-island and Egyptian cottons in the various cotton-growing tracts, (3) causes of red-leaf disease and several other related aspects, and obtained a number of important and useful results These results were compiled in two other monographs which were published by the Indian Central Cotton Committee in 1959 and 1960 Prof Dastur was in the process of constructing a theory for the application of fertilizers on the basis of a balance between nitrogen, phosphorus and potassium contents of the plant, and it is indeed unfortunate that death claimed him before he could complete this interesting and useful concept

Dastur had a reserved, but gentle and kindly disposition and shunned publicity, he virtually lived for his work and had little interest in social activities and scientific conferences which would take him away from it For his work on cotton in the Panjab he was made O B E. in 1946 He was a Foundation Fellow of the National Institute of Sciences of India and was elected president of the Botany Section of the Indian Science Congress in 1933 and of the Indian Society for Plant Physiology in 1959

He leaves behind a widow, a daughter, a son and a large circle of pupils and colleagues who will cherish his memory for a long time to come

R D Asana

NEWS and VIEWS

Post Office Radio Services Department:

Mr. T. A. Davies, O.B.E.

MR. T. A. DAVIES, inspector of wireless telegraphy in the Wireless Telegraph Section of the Radio Services Department of the Post Office, is to retire at the end of the year. Mr. Davies took a love of the sea to his job as head of the Wireless Telegraphy Section in 1948. This was to prove useful in his later work. After five years apprenticeship in the Royal Dockyard in his home city of Portsmouth, he obtained a first-class honours degree in engineering and joined the Post Office in 1925. While working in the Radio Branch of the Engineering Department he was able to use his knowledge of shipping in providing radio communications to ships and safety services for them while at sea. As inspector of wireless telegraphy he has been responsible for control and operation of the ship–shore services, inspection of ships' radio equipment, and the examinations for candidates for the Postmaster-General's Certificate. Twelve radio stations are administered from the headquarters in London.

Mr. R. Billington

MR. REG BILLINGTON has been appointed inspector of wireless telegraphy in the Wireless Telegraph Section of the Radio Services Department of the Post Office to succeed Mr. Davies. After obtaining an honours degree in the University of London, Mr. Billington worked in industry for two years before joining the Post Office Engineering Department in 1936. For a period during the Second World War he was seconded to the Iraq Government as chief engineer and returned to the Post Office in 1945, where he soon became an assistant inspector of wireless telegraphy. In 1948 he became deputy inspector.

Applied Electromagnetic Theory Section at the U.S. National Bureau of Standards

Mr. J. R. Johler

MR. J. R. JOHLER has been appointed chief of the new Applied Electromagnetic Theory Section, National Bureau of Standards, U.S. Department of Commerce. The section will be located in the Radio Systems Division at the Laboratories of the National Bureau of Standards at Boulder, Colorado. Mr. Johler's Section will be responsible for developing techniques for the solution of electromagnetic theory problems in terrestrial radio-wave propagation by numerical analysis, analytic and asymptotic series techniques, and will direct its work to electronic computer solutions. Much of the Section's work will be devoted to programmes of other Sections and Divisions in providing theoretical computations of propagation in various media. Since 1953, Mr. Johler has worked principally in the field of radio navigation systems evaluation, in low and very low frequency radio-wave propagation, and sferics (radio noise caused by lightning flashes). During 1953–55 he was responsible for the theoretical prediction of the performance of certain pulse-type radio navigation systems. Before joining the National Bureau of Standards in 1946, Mr. Johler had worked on the computational and engineering details of exterior ballistics at Aberdeen Proving Ground, Aberdeen, Md.

Atlantic Regional Laboratory, National Research Council, Canada:

Dr. A. C. Neish

DR. A. C. NEISH has been appointed director of the Atlantic Regional Laboratory of the National Research Council of Canada, at Halifax, Nova Scotia, in succession to Dr. E. Gordon Young. Dr. Neish studied at Nova Scotia Agricultural College, he obtained his B.Sc. (agriculture) from Macdonald College, majoring in agricultural chemistry, and his M.Sc. and Ph.D. (chemistry) from McGill University. His experience ranges from soils analysis and soils surveys at the Canada Department of Agriculture, and sessional lecturer, Department of Chemistry, McGill University (1942–43), to his research work with the National Research Council, first in the Division of Applied Biology (1943–48) and then with the Prairie Regional Laboratory at Saskatoon, Sask., where, in 1956, he was appointed head of the Physiology and Biochemistry of Plants Section.

Royal Society Expedition to Tristan da Cunha

THE Royal Society is to send a scientific expedition to examine the recent volcanic activity on the island of Tristan da Cunha in the South Atlantic. This activity is of considerable interest to geologists in Great Britain and the proposal is to mount an expedition which will include four or five geologists, leaving Cape Town some time during January 1962, to spend 2–3 months on the island. It is also proposed to include a zoologist and a botanist in the expedition to study any effects which the evacuation of the population of the island may have had on the flora and fauna. The expedition will be concerned not only with a detailed examination of the present volcanic activity but also to determine as accurately as possible the past geological history of the island. The scientific direction of the expedition is under the control of Prof. W. Q. Kennedy, professor of geology in the University of Leeds, with Prof. C. F. A. Pantin, professor of zoology in the University of Cambridge, as biological adviser, and with the co-operation of the Nature Conservancy.

H.M.S. *Jaguar* will be visiting Tristan da Cunha briefly later this month and advantage is being taken of this to send two geologists aboard the ship to make a preliminary investigation prior to the departure of the main expedition. These two geologists are Dr. R. W. Le Maitre, of the British Museum (Natural History), and Dr. P. G. Harris, of the Department of Geology, University of Leeds.

Science in Parliament

THE Parliamentary Secretary for Science, Mr. D. Freeth, dealt with a series of questions on science on December 5, ranging from nuclear energy, red deer stags on the Island of Rhum, engineering designers, strontium research, radioactivity, medical research on animals, the emigration of scientists, space exploration, the employment of scientists and the report on the long-term demand for scientific manpower. Mr. Freeth said that the Minister for Science is not satisfied with the present supply of engineering designers in Britain and he is in close touch with the President of the Board of Trade and trying to find ways to ameliorate the position The Department of Scientific and Industrial Research at present employs 170 scientists in Scotland, and it is intended to increase this number, subject to assessments of changing priorities and the resources available There are about 22,000 members of research associations, of whom a few belong to more than one association British plans for space exploration do not include projects for sending men into space

U K. Expenditure on Science, Technology and Education

In a written answer in the House of Commons on November 28, the Parliamentary Secretary for Science, Mr Denzil Freeth, said that the greater part of the expenditure on scientific and technological research in universities, estimated at £23 3 million in 1958–59 and £25 9 million in 1959–60, was met from the recurrent grants made by the Treasury on the recommendation of the University Grants Committee and was not separately identified Research Council grants to universities and to research units and institutes associated with universities amounted to £3 1 million in 1957–58, £3 5 million in 1958–59, £4 5 million in 1959–60, £6 million in 1960–61 and £8 2 million in 1961–62 In figures circulated for the Research Councils, with the exception of the Overseas Research Council, the grants from the Department of Scientific and Industrial Research are given as £1 315,000 in studentships and fellowships and £2,600,000 in research grants for 1961–62, the corresponding figures for 1960–61 being £1,050,000 and £1,490,000 For the Agricultural Research Council in 1961–62, studentships and fellowships amounted to £31,000, research grants to £157,000, expenditure of research units within universities £273,000 and grants to research units or institutes associated with universities, £1,011,000, for the period 1960–61, the figures are £24,000, £104,000, £299,000, and £931,000 For the Medical Research Council the corresponding figures are £115,000, £811,000, £1,526,000, and £317,000 in 1961–62, and £100,000, £620,000, £1,060,000 and £285,000 in 1960–61 For the Nature Conservancy, they are £21,000, £20,000, £11,000 under the first three headings in 1961–62, and £18,000, £11,000 and £7,000 in 1960–61

Replying to a question in the House of Commons on November 30, the Minister of Education, Sir David Eccles, said that the Ministry's present grant to the National Foundation for Educational Research was £7,000 and local education authorities were contributing £29,000 as members of the Foundation The Ministry was at present in discussion with the Foundation, and Sir David undertook to see that the availability of information was included

Toxic Chemicals in Agriculture

On December 5, the Joint Parliamentary Secretary to the Ministry of Agriculture, Fisheries and Food, Earl Waldegrave, announced publication of the report of the Research Study Group on Toxic Chemicals in Agriculture and Food Storage He said that the report concluded that protective measures now in force are generally successful, but affirmed the need for more fundamental and applied research in this field Earl Waldegrave said that the Government accepted the conclusions and intends to implement the Group's recommendations to the full extent of the additional resources which can be made available The Minister, Mr C Soames, made a similar statement in a written answer in the House of Commons on the same day, but, when pressed, neither he nor Earl Waldegrave would add to that statement In reply to further questions on December 7, Mr Soames said that he would be replying next week to the Select Committee on Estimates, which, in its Sixth Report of June 28, had recommended an inquiry into the effect on agriculture, public health and the ecology of Britain of all chemicals used in agriculture, and that he hoped that the restrictions on the use of cereal seed dressings containing aldrin, dieldrin and heptachlor which he had announced on July 3 would prevent casualties in future among wild birds and mammals His Department would intensify its survey of wild-life casualties as recommended by the Research Study Group, and consider after next session, with the interests concerned, whether any further action is necessary

The Commonwealth Scholarship Commission in the United Kingdom

The Commonwealth Scholarship Commission was constituted in December 1959 under the Commonwealth Scholarships Act, and in accordance with the proposed arrangements for administering in the United Kingdom the Commonwealth Scholarship and Fellowship Plan, recommended by the Commonwealth Education Conference in July 1959 and set forth in the White Paper presented to Parliament Pending the introduction of the relevant legislation and to facilitate the speedy implementation of the Plan, the Secretary of State for Commonwealth Relations had already appointed an interim committee, with Sir Eric Ashby as chairman, which met three times before the Commission held its first meeting on February 23, 1960, under the Earl of Scarborough as chairman, Sir Eric Ashby being then elected deputy chairman Confirming the preliminary arrangements made by the interim committee, the Commission endorsed the view that in the first year attention should be concentrated on the selection of Commonwealth Scholars and invitation for senior Commonwealth Fellowships deferred for a year. According to the first annual report of the Commission, up to the end of April 1960, 452 applicants were nominated by overseas agencies from some 5,177 applications received, and from these a Selection Committee recommended 219 candidates to the Commission, of whom only 178 accepted the offer of scholarships (Cmnd 1541 Pp 26. London H M S O, 1961 1*s* 6*d* net) Of these, 37 were from India, 17 each from Pakistan and Canada, 16 from Nigeria, 15 from Australia, 10 each from New Zealand and South Africa, and 8 from Hong Kong. Of these again, 74 were in the humanities, 50 in science, 33 in technology and 21 in medicine The chief considerations in selection were intellectual merit and a realistic and practicable plan of study, but selections were also made so as to ensure that the various parts of the Commonwealth are appropriately represented Applications have also been invited from candidates in the United Kingdom for awards offered by Canada, Australia, New Zealand, South Africa, Malaya, East Africa and Hong Kong, and scholarships have been offered by Canada to 13 candidates nominated

Exchange of Students for Technical Experience

The fourteenth annual report of the International Association for the Exchange of Students for Technical Experience reports continued growth in 1961, with three new members—Argentina, Luxembourg and the United Arab Republic—7,478 students exchanged, compared with 6,430 in 1960, and 3,265 employers offering training, an increase of 229. Since its foundation the Association has provided 59,769 students with technical training abroad. Exchanges of civil engineering and forestry students have increased considerably, but the exchange is still concentrated in a few European countries, and Germany, which received 1,757 students, with Great Britain and Sweden, represents more than 50 per cent of the training possibilities. Some 569 universities and colleges are now participating and 45 faculties are covered. These institutions and the participating firms are listed in the report by countries.

The corresponding report of the United Kingdom Association, which was established as an independent organization as from October 1, 1960, covers the year ending September 1961. During the summer vacation of 1961, 894 students were sent abroad for experience and 965 overseas students received and placed in British industry and commerce with the help of 389 British firms and organizations, compared with 883 and 908, respectively, in 1960. Of the students coming to Britain, Sweden (225), Germany (108), Netherlands (86), France (79) and Canada (57) sent the largest numbers, and of those received Sweden took 178, Germany 139 and France 117 (Fourteenth Annual Report, 1961. Pp. 79. Report of IAESTE in the United Kingdom for year ending September 1961. Pp. 14. London: International Association for the Exchange of Students for Technical Experience (U.K.), 1961).

History of Science and Technology at the Imperial College, London

Much thought is being given to-day, by those responsible for the education of scientists and technologists, to the best means of broadening their education and preventing excessive specialization. The Imperial College of Science and Technology is attacking this problem in various ways. A new development is now being added to those already in existence. A chair is being instituted in the history of science and technology which will result in a department for research and study of this subject in its own right, no exactly similar chair exists in a British university, although there are chairs elsewhere in the history and philosophy of science. The field of study, which is intentionally being made wide, will it is hoped embrace both the genesis of basic ideas and tools and the recent history of science and technology, the latter particularly because of the great acceleration in applying scientific discovery with important social and political results. The aim will be to teach scientists and engineers, rather than students of history, so that they become familiar with the background of major discoveries and inventions. To this end, the Department will start by providing postgraduate courses, both full-time and part-time. Later, it is hoped, optional undergraduate courses will be introduced in the third year of some degree courses. A generous contribution towards the cost of maintaining the new Department has been made by Imperial Chemical Industries, Ltd., which has recently supported the study of the history of technology by subsidizing some valuable publications. The establishment of the new Department will present both scientists and historians with a challenge, the first holder of the chair will have the opportunity to bridge one of the gaps between the humanities and the sciences. The results of this development will be watched with interest.

United Kingdom Fire Statistics, 1960

Since the Department of Scientific and Industrial Research and Fire Offices' Committee Joint Fire Research Organization began its statistical record in 1946, the number of fires in buildings occurring annually in the United Kingdom has almost doubled and, in 1960, was more than 62,000. The total number of fires of all kinds reached a peak in 1959 when, due to an exceptionally dry summer, a very large number of outbreaks occurred in the open. However, the figure for 1960, 133,484, is second only to that for 1959. These figures are revealed in *United Kingdom Fire Statistics 1960: Statistical Analysis of Report of Fires Attended by Fire Brigades in the United Kingdom during 1960*, which has recently been published as the first of an annual series made available to the general public (Pp. 106. London: H.M.S.O., 1961. 12*s*. 6*d*. net). This volume presents tables of figures relating to the origin and extinction of fires and to resultant casualties. Separate series are given for England and Wales, Scotland and Northern Ireland, and summary tables for the United Kingdom as a whole afford comparisons with previous years back to 1956. In the last-named section graphs are given of the annual and monthly incidence of fires, and there is a special graphical analysis of fires associated with space heating during the period 1949–60, this being a major cause of fire, particularly in dwellings. A marked downward trend in occurrences due to fires in open grates has been offset by a sharp rise in fires caused by oil-burning heaters, but the latter have been checked in the last year of the period under review. It is encouraging to note that the Fire Brigades are apparently relying increasingly on hose reel equipment for the first attack on fires and that this is proving adequate in a large proportion of cases. This should result in a continued reduction in water damage, although it is not possible to obtain figures to illustrate this point.

Dairy Research in Australia

In the small space of twelve short pages the Dairy Section of the Australian Commonwealth Scientific and Industrial Research Organization, led by Mr. G. Loftus Hills, presents a succinct account of its work for the year 1960–61 (Annual Report for the year ending June 30, 1961. Pp. 18. Melbourne: Commonwealth Scientific and Industrial Research Organization, Dairy Research Section, 1961). With a staff of about fifty people, of whom some twenty are graduates, the scope and value of the work now being done by the Section are very considerable. The topics under investigation include the mechanization of cheese-making, the surface deterioration of butter resulting from oxidative effects of the copper present in the parchment in which it is wrapped, and problems encountered in the manufacture of casein. The main buyers of Australian casein are paper manufacturers in the United States and Japan, where it is used for coating art paper, but this outlet for Australian casein is threatened by competition from soya bean proteins and from synthetic substances which give solutions of lower viscosity and which therefore allow the coating process to be done more rapidly than is at present possible with casein solutions. In an endeavour to solve this problem a detailed study is being made of the factors that affect the viscosity of casein solutions. A series of investigations, extremely important not only in dairying but also to many other branches of the food industry, is that concerned with flavour chemistry. The object of this work is to determine what carbonyl and other compounds are responsible for the various off-flavours, such as oily, tallowy, fishy and cardboardy, that can occur in certain circumstances in dairy products, and, if possible, to isolate and characterize the substances concerned. Marked progress has already been made in that direction. The report ends with a list of twenty-nine papers published during the year, some in the British *Journal of Dairy Research*, but most of them in the *Australian Journal of Dairy Technology*. Judging from this impressive list of publications, the Dairy Section of the Commonwealth Scientific and Industrial Research Organization can certainly claim that it had a satisfactorily fruitful year in 1960–61.

Strangers' Hall, Norwich

During the past year, four rooms on the street front of Strangers' Hall have, with the help of a Carnegie Grant, been converted into period rooms. On the ground floor is a kitchen with furnishings of about 1830 and a Georgian sitting-room. These rooms are seen from the street, but visitors do not go into them. On the first floor is a Victorian night nursery of about 1880 and a Victorian sitting-room of about 1860. Visitors walk along a roped pathway through these rooms.

Field Studies Council: Courses for 1962

The programme of courses for 1962, organized under the auspices of the Field Studies Council, has recently been issued. Such courses vary from those suitable for pupils below sixth-form level to those for university students, teachers and amateurs. Most natural-history subjects are covered. They are held at the following Field Centres: Slapton Ley, Kingsbridge, Devonshire, Preston Montford, near Shrewsbury, Malham Tarn, near Settle, Yorkshire, Juniper Hall, Dorking, Surrey, Flatford Mill, East Bergholt, near Colchester. Further information can be obtained from the wardens of these Field Centres or from the Publicity Secretary, Field Studies Council, Ravensmead, Keston, Kent.

University News: Glasgow

The following have been appointed to lectureships: Adam Fleck (biochemistry), N J McCorkindale, I C McNeill, K C Campbell and A L Porte (chemistry); W T. Morton (experimental physics), and D L Pursey (theoretical physics). A J Baker has been appointed Glaxo Fellow in chemistry, other fellowships have been awarded to G L le Bouvier, June Dixon and K R Dronamraju (genetics), John Cumming, A W Hendry and J G Lynch (nuclear physics), Robert McCrindle, M B Meyers and R D H Murray (organic chemistry), R M Turnbull (physics), and J. D. Roycroft (solid-state physics).

An Associated Electrical Industries (*RS*2) high-resolution nuclear magnetic resonance spectrometer (the cost of which was defrayed by the Department of Scientific and Industrial Research) is now in operation in the Chemistry Department.

For the present session, 392 students (292 men and 100 women) have been admitted to the science departments compared with 396 in 1960. The total of matriculated students in the University as a whole now stands at 6,765, compared with 6,600 in 1960.

London

Prof. Michael Abercrombie, professor of embryology in University College, has been appointed to the Jodrell chair of zoology and embryology at that College from October 1, 1962, in succession to Prof. P B Medawar (*Nature*, 187, 991, 1960).

The following appointments to readerships have been announced: Dr J R Butler (pure geochemistry) at the Imperial College of Science and Technology, Mr J. C G Coleridge (physiology) at the Royal Free Hospital School of Medicine, Dr S J. Taylor (mathematics) at Westfield College, Mr S. B Watkins (chemical engineering) at King's College, Dr. F W O'Grady (bacteriology) at St Bartholomew's Hospital Medical College, Dr. J. C Anderson (electrical engineering) in the Imperial College of Science and Technology.

The title of professor has been conferred on Mr J K T L Nash (civil engineering), in respect of his post at King's College, Dr H E Rose (powder technology), in respect of his post at King's College, Dr J H Westcott (electrical engineering), in respect of his post at the Imperial College of Science and Technology. Titles of reader have been conferred on Dr K W Gruenberg (pure mathematics) in respect of his post at Queen Mary College, Dr. J. M Zarek (engineering science) in respect of his post at King's College.

Announcements

The French Minister of Agriculture has conferred on Sir John Russell, formerly director of Rothamsted Experimental Station, the honour of Commander of the Order of Agricultural Merit on the occasion of the bicentenary of the French Academy of Agriculture.

Sir Charles Dodds, director of the Courtauld Institute of Biochemistry at the Middlesex Hospital Medical School, London, and a governor of the Lister Institute of Preventive Medicine since 1956, has been appointed chairman of the Governing Body of the Lister Institute, in succession to Sir Henry Dale, who has resigned after occupying that office for twenty years.

The Bradford Chemical Society and the Department of Chemical Technology of the Bradford Institute of Technology, in conjunction with the Yorkshire Council for Further Education, are organizing a symposium on "Antibiotics and Newer Synthetic Drugs", to be held at the Bradford Institute of Technology on February 10. Further information can be obtained from Dr R P. Sheldon, Department of Chemical Technology, Bradford Institute of Technology, Bradford.

The sixteenth annual symposium on fundamental cancer research, entitled "Conceptual Advances in Immunology and Oncology", is to be held in the University of Texas during March 1–3. Subjects under discussion will include theories of antibody production, control mechanisms of antibody synthesis, the nature of the antigen–antibody reaction, transplantation and immunological tolerance, and cancer specific antigens. Further information can be obtained from the Editorial Office, M D Anderson Hospital and Tumor Institute, University of Texas, Houston 25, Texas.

Erratum. In the communication entitled "Riometer Observations during a Solar Eclipse", by M A Gordon, in *Nature* of October 21, p 249, the legend to Fig 1 requires amendment: for "27 5 Mc /sec. radio wave" read "27 5 Mc /sec. (day) radio wave".

THE NEW MATHEMATICS AND OCEANOGRAPHY BUILDING OF THE UNIVERSITY OF LIVERPOOL

A FEW weeks ago the University of Liverpool took over from the building contractors (Messrs. Gilbert-Ash, Ltd) an almost completed Mathematics and Oceanography Building, the architects of which are Bryan and Norman Westwood and Partners, of London The building, which will cost about £260,000, has three wings, one on each of three sides of a grass-covered central courtyard, the remaining side of the courtyard will, at some later time, be open to one of the pathways of what will then be the University Precinct

The main wing is a gracious six-storeyed structure of glass, black concrete pillars, and white concrete panels of special design On the flat roof there is a 'wood and glass' penthouse in which the transcendental verities may be contemplated in relative comfort Below the building is a basement for the usual services, and farther below still there is the area boiler house

On the ground floor of the main wing, which is well set back from the road, and which is approached along a covered pathway traversing the courtyard, there is a spacious white-walled, airy, bright, central hall, the floor of which is made of attractive grey-green slate On one of the walls of the hall there is a five-panel mural inspired by the users, designed by John McCarthy, and executed by him in red terossa ferrata. This mural represents, in various groups, the history and development of mathematics, and many of the important branches of human activity in which pure and applied mathematics play, or have played, a significant part In addition, the hall contains a tall black-concrete abstract mural designed and executed by Eric Peskett Leading off the central hall there will be, when completed, the two principal lecture rooms of the new building The rooms will be large enough to hold audiences of 110 and 145, respectively, and they will be named after A. R Forsyth and J Proudman, the first professors of pure mathematics and applied mathematics of the University of Liverpool Proudman was afterwards transferred to the University chair of oceanography, and did much to give the Department of that subject its high reputation, it is therefore a particularly happy arrangement whereby the Departments of Mathematics and Oceanography are now housed in the same building

The first and second floors contain lecture rooms, the third floor contains more lecture rooms as well as the Sub-Department of Mathematical Statistics The fourth floor contains private rooms for the applied mathematics staff, and the fifth floor has similar rooms for the pure mathematics staff, as well as rooms for research students

At ground-floor level, at right-angles to the main block, there is a single-storey wing containing the Oceanography Laboratories, these are used for research and for instruction for honours under-

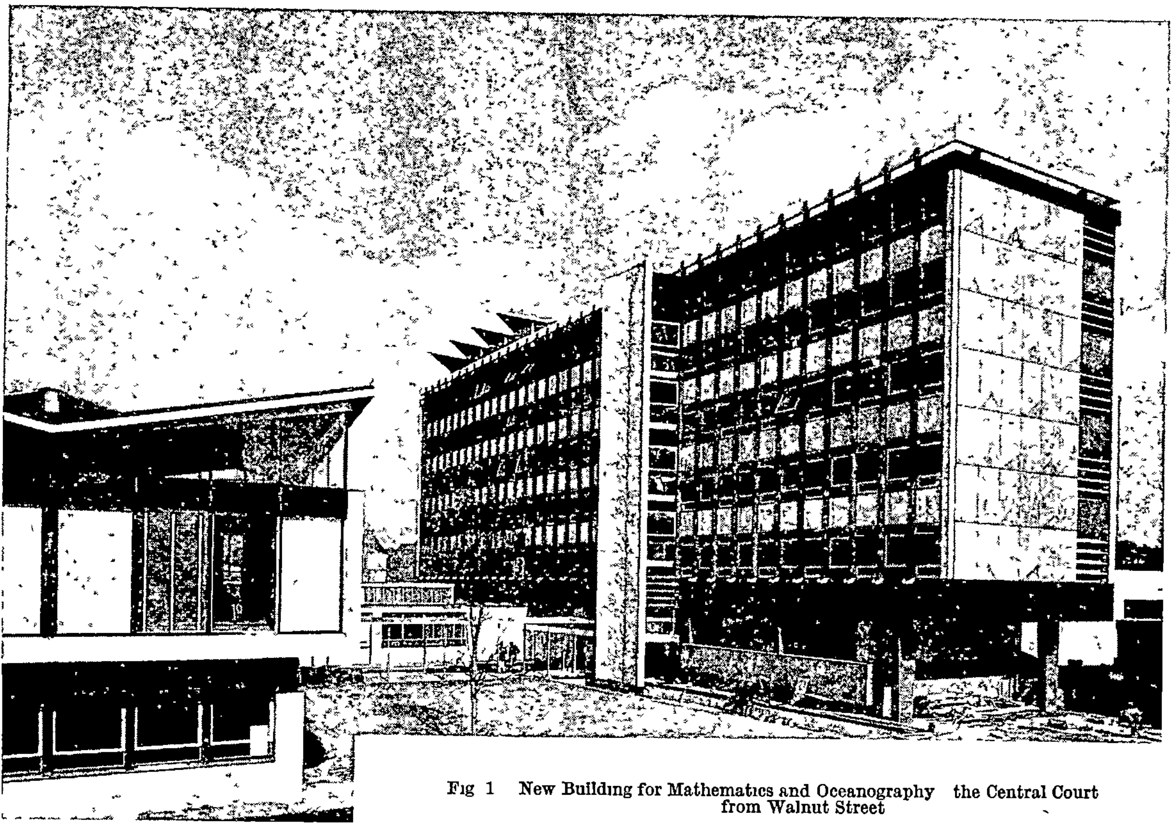

Fig 1 New Building for Mathematics and Oceanography the Central Court from Walnut Street

graduates. There are four main laboratories, two for physical work and two for chemical. Other rooms, such as a spectrographic room, balance room, dark room, workshop and store, are provided for special purposes. The laboratory accommodation and equipment offer facilities, on the chemical side, for work on the analysis of sea-water, particularly of trace elements by spectrophotometric methods, and on the composition of marine sediments. On the physical side, there are facilities for developing and testing apparatus for measuring, for example, the temperature and electrical conductivity of sea-water, and the velocity and turbulent fluctuations of currents.

At right angles to the single-storey wing, parallel to the main wing, there is a two-storey block containing, at one end, staff rooms and a combined library and chartroom for oceanography. The remainder of this block is occupied by the Sub-Department of Numerical Analysis, which possesses, in addition to rooms for its staff, others which house an electronic computer and its ancillary equipment, and a mathematical laboratory.

The building was designed to cater for the estimated number of science and engineering students, and the appropriate staff, likely to study mathematics in one or more of its aspects, or oceanography, within a total student community of 5,000. The erection of the building had scarcely been begun, however, when, under the stimulus of revised estimates of national requirements, the University agreed to plan its development on the basis of an ultimate student population of about 7,000. Large as it appears to be, therefore, the building will probably not be big enough to meet the demands likely to be made on it towards the end of the 'sixties.

The research carried out by the staff and graduate students of the Department of Pure Mathematics (Prof. A. G. Walker), the Department of Applied Mathematics (Prof. L. Rosenhead), with its Sub-Department of Mathematical Statistics (R. L. Plackett, reader in mathematical statistics), and its Sub-Department of Numerical Analysis (Dr. A. Young, reader in numerical analysis), and the Department of Oceanography (Prof. K. F. Bowden) covers a very wide range. The work that is going on in oceanography has been mentioned earlier; in pure mathematics research interests include classical analysis, group theory, algebraic and differential geometry and topology; and in applied mathematics work is being done on fluid motion, acoustics, quantum theory, nuclear physics, theoretical chemistry, astronomy, geophysics, numerical analysis and mathematical statistics.

The facilities of this well-co-ordinated group of teachers and research workers will be increased within the next few years when, with the aid of the grant recently promised by the University Grants Committee, an English Electric *KDF*9 Computer will be obtained to replace the existing *Deuce* of the Computer Laboratory, which was bought with funds provided by local industrialists and the University Council.

The University skyline at the top of Brownlow Hill is changing significantly—new buildings for physics, chemistry and veterinary science have been erected; still more buildings are going up for chemistry—and the foundations of engineering buildings as well as those of an extension of the Students' Union are now being laid. Within this complex of building activity the white-walled Mathematics and Oceanography Building stands out as something rather different and aloof, but the building will, we hope, serve as a university focus of mathematical thinking, teaching and research, and a centre from which mathematical service will flow to the University as a whole—as well as a place where important work on oceanography will be carried out.

L. ROSENHEAD

OXIDATION PROCESSES IN CHEMICAL MANUFACTURE

THE two-day symposium on "Oxidation Processes in Chemical Manufacture" organized by the London Section of the Society of Chemical Industry, was held in the William Beveridge Hall of the University of London during September 28–29, and attracted an audience of some 250 scientists from industry and the universities—with many overseas members.

The remarkable development in industrial oxidation processes over the past decade is perhaps best illustrated by the fact that while six comparatively new processes were discussed in some detail by the speakers, an equal number were mentioned only in passing. Among the latter were the direct oxidation of ethylene to ethylene oxide, the oxidation of propylene to acrolein, the subsequent oxidation of acrolein to glycerol, the direct oxidation of propylene in the presence of ammonia to acrylonitrile, and the production of hydrogen peroxide by the peroxidation of isopropyl alcohol. The processes chosen for discussion were the direct oxidation of ethylene to acetaldehyde, the vapour phase oxidation of acetaldehyde to peracetic acid, the uses of hydrogen peroxide in industrial oxidations with particular reference to epoxide formation, recent developments in the oxidation of aromatic hydrocarbons and the recovery of chlorine by oxidation of hydrogen chloride. Theoretical work on liquid-phase oxidation of organic compounds, vapour-phase oxidation of hydrocarbons and liquid phase oxidation catalysed by soluble metal salts was also discussed.

The direct oxidation of ethylene to acetaldehyde in the presence of a palladium chloride–copper chloride catalyst was described by Dr. Smidt (Consortium für Elektrochemische Industrie G.m.b.H.) as a single-stage reaction possibly applicable to other olefines. The mechanism of the reaction in the case of ethylene involves the formation of a complex between ethylene and palladium chloride. The resulting complex decomposes to give acetaldehyde, the palladium metal being precipitated. Since the decomposition of the complex is inhibited by acids, it is suggested that the first step in the reaction is the addition of a hydroxyl ion to the complex-bound olefine. In the second stage the π electron pair of the olefine passes over completely to the palladium with simultaneous migration of an hydride ion from carbon 1 to carbon 2. A double bond is then formed between carbon atom 1 and the oxygen of the hydroxyl group with expulsion of proton. On this hypothesis the oxygen required for the oxidation of the olefine is supplied by the water, and only the oxygen atom from the water passes over to the olefine during the reaction, all four hydrogen atoms originally present in the ethylene remaining in the aldehyde This is in contrast to the suggested mechanism discussed by Moiseev and co-workers Unpublished work of Dr Kreckeler of Farbwerke Hoechst has, however, shown that decomposition of the dinuclear ethylene–palladium chloride complex by heavy-water yields acetaldehyde which does not show any deuteration in mass spectrographic examination

The commercial development of the reaction to a continuous process required the precipitated palladium metal to be re-oxidized after reaction 1

$$C_2H_4 + PdCl_2 + H_2O = CH_3CHO + Pd + 2HCl \quad (1)$$

$$Pd + \tfrac{1}{2}O_2 + 2HCl = PdCl_2 + H_2O \quad (2)$$

The addition of cupric chloride enables the second step of the process to be carried out since cupric chloride readily oxidizes the finely divided palladium and the cuprous chloride so formed is quickly re-oxidized to the cupric state The overall reaction may then be written

$$C_2H_4 + 2Cu^{2+} + 4Cl^- + H_2O \xrightarrow{Pd\,Cl_2} CH_3CHO + 2H^+ + 2(CuCl_2)^-$$

the cuprous chloride being reoxidized by air

In the commercial process, as outlined by Dr Smidt, ethylene reacts with the catalyst solution, under moderate pressure and medium temperatures, in a flow reactor to 99 per cent conversion After releasing the pressure of the catalyst solution the acetaldehyde formed distils off (the reaction heat being sufficient to accomplish this), and the reduced catalyst solution is pumped to the oxidation reactor when it is regenerated by air and returns to the ethylene reactor Further details of this elegant process will be awaited with great interest

The development of a commercial process for the manufacture of peracetic acid by the vapour phase oxidation of acetaldehyde was described by J A John and F J Weymouth, of Courtaulds, Ltd , and British Celanese The major problem associated with this development was the explosion hazard associated with the concentration of peracetic acid Experimental work established that concentrations of peracetic acid in acetic acid below 40 per cent peracetic acid were stable and that in the vapour phase excess acetaldehyde reduced the hazard to safe conditions Three pilot plants, each of increasing capacity, had been successfully operated and the process was now considered suitable for commercial exploitation The major industrial usage of peracetic acid developed in recent years is as an epoxidizing agent for the production of epoxy soya bean oil, epoxy tall oil esters, di*cyclo*pentadiene dioxide and the diepoxide from vinyl *cyclo*hexene

The production of hydrogen peroxide by the barium process or by electrolytic methods has been virtually replaced in Britain by the method based on the cyclic oxidation and reduction of 2-ethyl-anthraquinol The development of an alternative method of production by direct oxidation of isopropylalcohol in the United States will lead to increased availability of this material T D Manly of Laporte Chemicals, Ltd gave an account of the wide variety of industrially important chemical processes using hydrogen peroxide Supplied in tank-car quantities stabilized against chance impurities the modern product can be used at all strengths under many different conditions without suffering detectable loss by decomposition

The recent developments in the production of a variety of chemicals using aromatic hydrocarbons from petroleum or coal tar were outlined by R Landau and R W Simon The processes discussed included the manufacture of phthalic anhydride from naphthalene or *ortho*-xylene, maleic anhydride from benzene—or from butene although a direct comparison of these two processes was not given—liquid-phase oxidation of mixed xylenes to yield isophthalic, phthalic, terephthalic acids and the recently announced oxidation of pseudocumene to give trimellitic anhydride Brief mention was also made of the many processes now available for the production of phenol from benzene and of newer processes using *cyclo*hexane and *cyclo*hexanol obtained by hydrogenation of benzene and phenol respectively, for the production of adipic acid

An account of recent developments in the oxidative recovery of chlorine from hydrochloric acid by W F Engel, S Muller and M J Wade of the Shell Laboratory, Amsterdam, introduced an inorganic oxidation process—the Deacon process—into the discussion The increasing amounts of by-product hydrochloric acid produced in conjunction with the manufacture of chlorinated organic compounds coupled with the probability of an increase in the price of chlorine as the demand for chlorine increases beyond the so-called caustic-chlorine balance—has stimulated development of processes for the recovery of chlorine from the acid Three such processes have been announced recently, the De Nova electrolysis of hydrochloric acid operated by Monsanto, the oxidation by mixed nitric/sulphuric acid developed by the Institut Français de Petrole and the modified Deacon process described by Shell Several companies have suggested the use of a fluidized-bed technique using modified cupric chloride catalysts The Shell process employs a modified cupric chloride catalyst supported on silica in a fluidized bed at temperatures between 350° and 360° C using air or oxygen Conversions of 76–77 per cent per pass are claimed On the figures presented the economics of the process are attractive

Theoretical aspects of oxidation process were reviewed in three papers Liquid-phase oxidation by molecular oxygen was reviewed by G H Twigg with particular reference to the oxidation of hydrocarbons and the reactions involved in the oxidation of cumene to phenol and acetone The extension of the general reaction mechanism to oxidation of aldehydes, ketones, alcohols and olefines while generally accepted does not entirely satisfy, and further work in this field is desirable Recent work on the oxidation of binary mixtures is likely to be of considerable theoretical interest The gaseous oxidation of organic compounds was discussed by C F Cullis with particular reference to the effects of temperature, pressure, surface catalysis and mixture composition on the course of oxidation of a particular starting material Investigations such as those reported on the vapour-phase oxidation of acetaldehyde to peracetic acid indicate that by careful choice of reaction conditions the reaction may be controlled to give, as final products, compounds which normally would occur only as intermediates in a more general oxidation It is, however, doubtful if the knowledge of low-temperature vapour-phase oxidation processes is sufficiently advanced to enable prediction of reaction conditions in particular cases to be made on the basis of generalized theory

The oxidation of organic compounds by metal ions and complexes was reviewed by H R Bacon with particular reference to complexes of silver and copper Recent work using argentic piccolinates to catalyse the oxidation of primary and secondary amines has indicated that the effectiveness of the metal ion may be modified by the nature of the ligand Comparison of reactions catalysed by cobalt, silver and copper complexes may lead to a better understanding of the reaction mechanism

The conference concluded with a general discussion of the relative merits of fluidized-bed versus fixed-bed reactors for oxidation reactions For those reactions, such as the modified Deacon process, in which thermal balance is readily achieved, the fluidized process is preferable In reactions liable to rapid heat evolution, leading to possible explosion hazard, fixed-bed reactors may be preferred although sufficient data on the successful application of the fluidized technique to such reactions are not yet available. F Morton

FAST REACTIONS IN PHYSICAL CHEMISTRY

THE first of the triennial Cambridge Physical Chemistry Summer Schools was held in August 1947 but the sequence was broken after 1956 by a gap of five years

Each school has been organized by Prof R G W Norrish and his colleagues in the Department of Physical Chemistry in Cambridge and this year Dr A B Callear and Dr B P Levitt acted as organizers. The topics were selected to form a composite pattern of ideas related to current researches in the Department Certain lecturers belonged to the Department, others were guest lecturers

The intention has always been to correlate facts and notions within the pattern chosen, to stimulate discussion, to invite, even to provoke, in a friendly way controversy, rather than to instruct by presenting the facts, figures and theory as finished uninspiring blocks of knowledge which could well be posted in cyclostyled form The pattern for the 1961 School was "The Study of Fast Reactions"

Dr T M. Sugden (Cambridge) dealt effectively with the recent developments in the collision and transition state theories, a matter of constant concern with so many chemists in industry and college alike In his energetic, elusively 'off the cuff' manner, he analysed the processes of energy exchange with special reference to fast reactions, unimolecular decomposition of polyatomic molecules and the recombination of atoms It may be well imagined that there was much animated discussion during the half-hour coffee-break.

Dr Sugden described the photometric investigation of flames He referred to experimental techniques for the measurements of H-atom, O-atom and OH— group concentrations in flames Significances of the method included the determination of bond strengths in molecules such as M—Cl, M = Mn, Ni, etc Trends into the future were not neglected. In another talk, Dr Sugden dealt with chemical reactions in the upper atmosphere. Methods of investigation of temperature, density, pressure, and composition gradients and the reactions occurring in different strata are bound to attract quickly growing interest in coming years

Reactions in shock waves were discussed by Dr A G Gaydon (Imperial College of Science and Technology), who outlined experimental methods of observing the emission spectra and temperatures of shock-heated gases Vibrational relaxation times of nitrogen and carbon monoxide, and the measurement of dissociation-rates of oxygen, hydrogen and carbon dioxide were other points of lively interest to the non-expert as well as to the expert listener In another lecture, Dr Gaydon discussed the advantages of low-pressure flames for the study of reaction zones, referring to the identification of reactive intermediates by emission spectra of flames, to the measurement of temperature by study of rotational structure of bands, the reversal of spectral lines and to reactions in hydrocarbon flames

Chain reactions in gases, especially those leading to the ignition of gases, were discussed by Dr P G Ashmore (Cambridge), who has taken part in a number of previous Schools Theories of ignition limits and of induction periods were discussed with reference to non-branching and branching chain reactions

Ultra-violet spectroscopy and fluorescence was dealt with by Dr A B Callear (Cambridge), who opened with a helpful reminder on the use of term symbols and mode of coupling of angular momenta in atoms Information on spin-orbit relaxation can be gained from examination of the quenching of the fluorescence of sodium and mercury Rate of vibrational relaxation of electronically excited I_2, S_2 and NO was referred to

Evidence for ions in flames was presented by Dr D R Jenkins (Cambridge), who outlined experimental methods for the determination of distribution of ions by means of Langmuir probes, microwave and radiowave attenuation and mass spectroscopy

Relaxation in liquids was the title of a lecture by Prof. J Lamb (Imperial College of Science and Technology), who outlined the fundamental theory of acoustic relaxation to what must have been many new attentive ears. The potentialities of the method were amply illustrated in a very convincing way.

Techniques for the measurements of fast reactions in solution were considered by Dr R H Prince (Cambridge), who gave a lucid survey of mechanism and reactivity revealed by a study of fast reactions in solution Substitution reactions in organometallic and co-ordination compounds, redox reactions, rapid isotope exchange were mentioned in particular

Kinetics of fast reactions in solution was the title of the lecture by Dr E A Moelwyn-Hughes (Cambridge), who, in his inimitable and stimulating way, brought freshness to the ever-difficult problems of rate data and transition-state characteristics Interpretation of rate data as a function of temperature, certain limitations of the transition state formulation and the derivation of equations used in the interpretation of relaxation of ionic equilibria were critically commented on

The lecture on fast electrode reactions by Dr G C Barker (Atomic Energy Research Establishment, Harwell) was a very helpful contribution. He considered the theoretical basis of the measurement of rapid redox reactions which occur at the electrolyte/electrode interface and remarked in useful detail on experimental methods involving single-step square-wave pulses and Faradaic rectification.

Not quite in the pattern but timely and very helpful was the talk on high-speed gas chromatography by Dr. J H. Purnell (Cambridge) Factors determining the correlation between the speed of a gas chromatographic analysis and the efficiency of the process were examined in a cursive and conciliatory way, appropriate in dealing with a technique which is still much of an art. If necessary, remarkably short analysis times, less than 1 sec, could be achieved, and are attractive in the study of gas reactions

Work on isothermal reactions of atoms and radicals by flash photolysis was discussed by Prof R G W Norrish, who illustrated the applicability of the techniques of flash photolysis in the detailed scrutiny of very fast reactions in gases In the last lecture of the School, he went into the matter of the chemistry of combustion as revealed by kinetic spectroscopy, showing the applicability of flash photolysis in the investigation of adiabatic processes Anti-knock action of tetraethyl lead was related to the appearance and disappearance of lead oxide and lead during explosion

Time for discussion was allowed at the end of each lecture and indeed there were some astute points put. There was animated and valuable discussion during the long coffee-break in the morning and during the afternoons, which were in the main devoted to visits to the laboratories and to a lecture at 5–6 p m. There were social meetings when easy exchange of ideas was stimulated

An outstanding feature was the well-organized social life of the School, and in this Mrs Norrish and other ladies had doubtless been influential There were some 120 members from industry and colleges and quite a number were from overseas

W. GERRARD

METALLURGY OF BERYLLIUM

BERYLLIUM has only emerged as a metal of industrial significance during the past few years Even now, its use is not securely established and is faced by a number of real difficulties The following assessment of its present position is based on seventy papers presented at an international conference arranged by the Nuclear Energy Committee of the Institute of Metals and held in London during October 16–18

The potential applications of beryllium at present lie in two main fields—aircraft, missiles and spacecraft on the one hand, and atomic reactors on the other. In the first, the advantageous properties of beryllium are its high-strength-to-weight ratio, high elastic modulus, specific heat and thermal conductivity and moderately low coefficient of expansion. With a density of 1 85 and a tensile strength of 50–70,000 lb./sq in, beryllium has a superior strength/weight ratio to all other metals up to about 350° C, although some of the recently developed high-strength stainless steels are not far behind. However, this is not beryllium's greatest attraction. Elastic stiffness and resistance to buckling under compression rather than tensile properties are the limiting factors in many design problems in this aeronautical and spacecraft field, and it is in this that beryllium's combination of low density and high modulus of elasticity ($E = 43 \times 10^6$ lb /sq in) is outstanding Thus, for example, a box beam designed in beryllium to resist a buckling load at up to 450° C is only about half as heavy as one in titanium alloy and about one-third as heavy as one in a high-strength stainless steel In addition, the high specific heat and thermal conductivity and the low coefficient of expansion are important in minimizing the effects of aerodynamic heating With these properties, "beryllium holds one of the keys to a successful flight to the moon" (I Perlmutter, Wright-Patterson Air Force Base)

For atomic reactors, on the other hand, the attraction of beryllium lies in its low neutron adsorption, and at present there is wide investigation of its possible use as the fuel element can in high-temperature, gas-cooled reactors In addition, the Australian Atomic Energy Commission is examining the use of beryllium, instead of graphite, as a moderator in low-power reactors on the grounds that this would permit smaller reactor cores and possibly reduce over-all cost It is also considering fuel elements in which the fuel, for example $(U,Th)Be_{13}$, is dispersed in beryllium

Unfortunately, these attractive properties are accompanied by two immediate disadvantages Beryllium is very costly, billets are about £20 per lb The United Kingdom is not a producer; supplies come from Pechiney and from the United States Secondly, there is a severe health hazard. Inhalation of the metal or its compounds produces acute chemical pneumonitis, or, at lower doses, a chronic lung disease, berylliosis. To keep the beryllium content of the air at safe levels, special workshops are required with air extraction and filtration, and total enclosure of some machines Monitoring of the beryllium-levels and health checks are necessary. However, the applications suggested for beryllium are those that can withstand a fairly high cost and, once a beryllium-handling facility has been established, the health-hazard is not too troublesome. There remains a third disadvantage, that of brittleness, and at present this is the major problem in the metallurgy of beryllium Practically every paper read at the conference in London was to some extent concerned with brittleness

Beryllium is quite ductile at normal hot-working temperatures of 1,000°–1,050° C, so hot-fabrication processes do not present any great difficulty However, below about 200° C there is a fairly sharp transition to a low ductility This not only means that fabrication by cold-work is difficult or impossible, but also, and more important, that in service high stresses, perhaps purely local, that might be relieved by plastic distortion, lead instead to fracture

This transition to brittleness is accompanied by a transition in fracture mode from so-called 'ductile fracture' to a process of separation along definite crystallographic planes, the cleavage planes Thus, the brittleness of beryllium appears to correspond to the classical brittle fracture of mild steel that has caused so much concern and investigation since the 'Liberty' ship failures during the War.

Investigations of mild steel have brought out the importance of two stages in the development of cleavage First, the initiation of a crack by some process such as the coalescence of the dislocations in a slip plane through compression against a grain boundary, or by the coalescence of dislocations through interaction with others on an intersecting slip plane or by twinning. Secondly, the breakout of this dislocation crack across a cleavage plane in the manner of a Griffith crack propagated by the externally applied stress. It is considered that the transition to cleavage occurs when the criterion for propagation is fulfilled.

This criterion involves three factors. First, the size of the dislocation crack depends on the number of dislocations forming the crack and therefore on the grain size. The smaller this size, the smaller the dislocation crack and the more difficult is cleavage. Secondly, the effective surface energy associated with crack growth represents partly the true surface energy and partly the plastic work arising from the operation of dislocation sources in the region of stress-concentration surrounding the growing crack. The easier dislocation movement, the greater the amount of plastic work, the shorter the initial dislocation crack and the more difficult its propagation. Thus, a high effective surface energy arising from easy dislocation movement favours ductility. Thirdly, the applied stress available for crack propagation is determined by the flow-stress at the instant of fracture. The reason why low temperature favours cleavage is that the flow-stress is then higher and the effective surface energy lower because dislocation movement is more difficult. The papers at the conference showed that the conclusions from the work on steel have now been applied at least qualitatively to beryllium.

The attempt to overcome brittleness by a fine-grain size at present divides beryllium work into two categories, powder and ingot. Present industrial producers of beryllium components start from powder, and the oxide derived from the coat on the particles inhibits the growth of grains during sintering and annealing. In this way, the grain size can be kept to about 50μ. Others, notably the group headed by G. C. Ellis, A. J. Martin and A. Moore at Aldermaston, argue that powder methods yield an intrinsically poorer material with reduced high-temperature ductility and resistance to corrosion and they have put their effort into an attempt to obtain fine grain size in wrought material derived from an ingot. The difficulty lies in the easy growth of grains of this material on re-crystallization. So far, the finest grains, 40μ, have been obtained by 'flash annealing', that is, exposure for a few seconds to a temperature of 900°–1,000° C., well above the normal re-crystallization temperature, so that many nuclei are active. Such treatment is only possible with thin sections. However, even by normal re-crystallization it has now proved possible to keep the grain size at 60–80μ in material that has been worked as far as sheet. A full assessment of the mechanical properties of the products derived from ingot has not yet been obtained.

Another possible approach to reduced brittleness is through purification. This may be beneficial because of a reduction in the flow-stress available for crack propagation and an increase in the effective surface energy through easier dislocation movement. The beryllium obtainable commercially is not particularly pure; it contains a few hundred p.p.m. of various metals, mainly iron, aluminium, silicon and of non-metals, oxygen, carbon and nitrogen. A number of laboratory-scale attempts at purification by distillation and zone-refining were reported at the conference. A. R. Kaufmann *et al.*, for example, reduced the contents of the metallic impurities to the 1–5 p.p.m. range. There appeared to be a reduction in flow-stress and increase in ductility. However, the purification is difficult and consolidation of the product to a uniform, fine-grained polycrystalline state has not yet been achieved. Thus, at the moment there does not seem to be an immediate easy path to ductility through purification. Perhaps in any event it may be unsafe to expect too much from this approach in view of the thin-film electron microscope work of H. G. F. Wilsdorf and F. Wilhelm that showed strict confinement of the dislocations to crystallographic directions, suggesting that the intrinsic lattice resistance to dislocation motion (the Peierls–Nabarro stress) is already high, independent of impurity hardening.

Although the brittleness of beryllium seems to be essentially similar in principle to that of mild steel, it emphasizes a point that is not important with steel. Beryllium is close-packed hexagonal and suffers from a dearth of slip systems. At room temperature, slip on the single basal plane is by far the easiest; (10$\bar{1}$0) slip is 4–5 times as difficult. Neither of these contributes any component in the *c* direction. Thus, any one grain in a polycrystal experiences difficulty in deforming crystallographically in conformity with the matrix. Consequently, as brought out by J. Sawkill and by B. Allen and A. Moore, there is bending and kinking of the slip planes and this supplies, at least in some cases, the fracture nucleation mechanism. This is the one suggested a number of years ago by Orowan and by Stroh in which the discontinuity in displacement when slip crosses a bend plane produces cracking down the slip plane. A second effect of the dearth of slip planes is that wrought products such as sheet or extruded bar, which have received highly directional working, are strongly textured with the basal planes parallel to the direction of working. This has a marked effect on ductility. For example, cross-rolled sheet can show 30–40 per cent elongation in the plane of the sheet even at room temperature, but there is practically no ductility in the third dimension and such sheet readily fractures in forming processes. Thus, the control of texture is an important aspect of the brittleness problem. Some success in achieving a more random orientation in sheet has been obtained by the press-forging of beryllium encased in a steel container and afterwards rolling the flat produced (R. L. Craik and D. A. Barrow).

Another interesting approach to the problem of brittleness has been attempted at the Armour Research Foundation, Chicago. This is to use 'liquid-phase sintering' as in the common tungsten carbide–cobalt tools. The beryllium is dispersed in a continuous plastic matrix of silver–aluminium–germanium that is liquid at the sintering temperature and spreads around the beryllium particles. The product is quite ductile at room temperature, but Young's modulus is reduced to 22 × 10^6 lb./sq. in.

In addition to low-temperature cleavage, beryllium also shows a dip in ductility around 600° C. due to the occurrence of intercrystalline fracture. This is not so important as cleavage, and in any event it has now been shown at Aldermaston and other centres that annealing about 800° C. followed by slow cooling removes the brittleness produced at 600° C. The heat-treatment appears to over-age impurity precipitates and restores a proper balance between the ease of deformation within a grain and at a grain boundary.

Apart from this brittleness problem, two other problems appear when beryllium is used in a reactor In the carbon dioxide–water coolant mixtures, breakaway, that is, accelerating, oxidation can occur The papers at the conference did not add a great deal on this topic, although the Australian Atomic Energy Commission reported an inhibition of breakaway by oxidation of the beryllium powder at 800° C in oxygen prior to sintering Irradiation damage also occurs in a reactor The normal displacement of atoms by neutrons that is responsible for the damage in steel and copper has little effect in beryllium, and damage only appears at doses above about 10^{19} neutrons cm^{-2} when it is due to the helium generated by neutron reaction with beryllium. R S Barnes and others have shown that when present as small bubbles the helium leads to hardening and loss of ductility Larger bubbles accumulate at the grain boundaries and these promote fracture in creep They can also give grain boundary permeability, which is, of course, highly undesirable in a fuel can.

It is perhaps clear that there is no lack of beryllium problems However, considering the advances that have been achieved in the quite short period of really active interest, the future is not without hope

N J Petch

CHANGES OF CLIMATE

As was entirely appropriate for a symposium sponsored by the Unesco major project on scientific research in arid lands, an effort was made on the occasion of the recent meeting in Rome (October 2–7), arranged by Unesco and the World Meteorological Organization, to restrict the interest to climatic variations which have occurred since the latest glaciation, with particular attention to the period of the meteorological record The reason behind this decision was no doubt the wish to talk about something which might conceivably have relevance to the nature and trends of the arid lands of to-day—relevance on the scale of economic planning, say, for a hundred years At the same time this emphasis on what, after all, is micrometric on the geological scale served the purpose of almost eliminating the endless speculations on the causes of ancient climatic change, fascinating though they undoubtedly are Most geological, geophysical and astronomical happenings which are potential climatic controls, such as mountain building and denudation, drifting of the continents, changes in solar constant and a score of other possible processes, are eliminated when the time-scale is a mere 100 or 1,000 years

It should not be supposed, of course, that examination of such recent changes will throw much light on events on the longer time-scale The odds are that variability on each different scale of time presents an essentially different problem with an essentially different theoretical explanation But it is good to keep a symposium within bounds, and the short-period problem is the most tangible, the most suitable for the attention of the theoretical meteorologist, and the most important economically

More than forty papers were presented, divided into four sessions each of one day and treating respectively the period of the meteorological record (chairman, R G Veryard), the late geological and early historical period (chairman, K W Butzer), theories of recent climatic change (chairman, R C Sutcliffe) and significance of changes of climate (chairman, R O Whyte) A summing-up by C C Wallén on the last day was particularly well received

The first session was much helped by the chairman's fine survey of the literature, and the papers presented did not seem to take us very much further with the facts, although substantiating the main features now becoming generally familiar, in particular the warming of extratropical latitudes over the century ending about 1940 J M Mitchell's world-wide view of the evidence will be found particularly useful, most of the other contributions being local studies An effort was made to give attention to the statistical treatment of time series on the basis of a paper by R Sneyers, it being well known that a good proportion of the published literature on climatic change suffers from uncritical and undefined statistical standards The general technique of power spectrum analysis received mention but was not pursued. It was, however, evident that those in the field were very conscious of the problems

The second session fell mostly to the non-meteorological disciplines, geology, geomorphology, archæology and dendrochronology being represented Apart from the chairman's valuable introduction, the most persuasive paper was by R W Fairbridge on mean sea-level during the past 20,000 years It is remarkable and a little puzzling that such clear evidence should be obtainable from data which one would have thought to be confusing

Under the heading of "Theories of Changes of Climate", the papers were entirely by meteorologists, some of whom were new to the field This was a good feature, as a weakness of the subject is its failure to attract expert meteorologists aware of the complex behaviour of the atmosphere The chairman directed attention to the possibilities of variability through feed-back contained within the Earth–ocean system without necessarily recruiting the aid of extraneous factors, radiation, dust, carbon dioxide and the like, and other papers developed the theme both J Bjerknes and J Namias were on this side On the other hand, the most substantial paper was perhaps that by E B Kraus, giving the results of a heavy calculation nobly carried out on the effects of a radiation change on the general circulation The paper was more an illustration of the mathematical approach than a practical solution, but was important as being one of very few attempts that have yet been published

In the final session, L P Smith's paper on "The Significance of Climate Variations in Britain" was very much to the point, and anyone who previously had doubted whether the subject had any economic significance must have given way at this point

The broad impression created by the meeting is that, for the period of the instrumental record, the subject, which has got to a certain descriptive stage by pure empiricism is in danger of languishing for want of ideas Perhaps the symposium marks a turning point, and the attention which climatologists are giving to statistical techniques and which theoretical meteorologists are giving to the general circulation are pointers to the future For the longer record the interest must continue to rest on techniques of exploration and interpretation of evidence, and here there is no slackening of interest, for most of the Earth's surface is almost unexplored

The facilities provided by the Food and Agriculture Organization and the Italian authorities were admirable After several experiences of large meetings, one looks forward to those where headphones and simultaneous translations are provided To be able always to hear is a wonderful asset, even if the language presents no difficulty It is understood that the complete papers are to be published by Unesco and this will be worth while A good proportion of the material had been heard or read before, but there would be no sense in insisting on complete novelty for an interdisciplinary meeting where the object is to exchange ideas, not to be mutually incomprehensible R. C SUTCLIFFE

CHEMICAL WARFARE ON PLANT PESTS AND DISEASES

THE first British Insecticide and Fungicide Conference organized by the Association of British Manufacturers of Agricultural Chemicals was held at Brighton during November 7–9 under the presidency of Dr H. G Sanders, chief scientific adviser (agriculture) to the Ministry of Agriculture, Fisheries and Food It was truly an international gathering, for of the 470 delegates attending from official research stations, Government departments and manufacturing firms, nearly one-quarter came from fourteen countries overseas

The conference consisted of ten successive sessions devoted to important present-day problems in plant pathology and their possible solution by chemical means During the first two days each session began with one or more introductory papers by authorities on the subject under discussion, and these were followed by brief reports of relevant research in progress at various centres The morning of the third day was given over to research reports on new insecticides, fungicides and acaricides, and on novel formulations as well as new methods of application In the final session attention was appropriately directed to the problems involved in translating research into practice and in introducing insecticides and fungicides into agricultural practice both in Britain and overseas. In all, more than fifty papers or reports were presented from the research departments of official agricultural institutes and industrial firms, including a number from Holland, Germany and Italy

On introducing the president, Mr H C Mellor, the chairman of the Manufacturers' Association and of the conference, said that the industry is at present under fire, though much of the criticism levelled at it is uninformed. The members of his Association are as anxious as anyone to find safer chemicals, and are most careful to honour the agreements made on their behalf with the Ministry of Agriculture, as well as to satisfy the requirements of the Notification Scheme under which all new chemicals are notified to the Ministry for clearance before marketing.

In his opening address Dr Sanders referred to the increasingly important part played by chemicals in farming Unfortunately, some of them are toxic to mammals and wild-life, and this has led to alarm in the public mind. He believed that much of this concern is due to ignorance of the many hurdles new chemicals have to surmount before they are cleared for marketing by Government departments of health and agriculture. The present conference was mainly a scientific one, but the delegates included many whose functions were to translate science into practice, and it should therefore provide a good opportunity for getting things, including toxic hazards, into proper perspective Dr Sanders also commented on the close co-operation now existing between industry, research workers and Government officials, and expressed appreciation to the manufacturers for disclosing to him highly confidential information which has fully satisfied him that during the past five years there has been a very substantial reduction in the acreage sprayed with the more toxic chemicals, even though the total acreage sprayed has doubled during that period

The first session was concerned with soil pests and diseases of agricultural crops, and included a review by Dr Hubert Martin (until recently director of the Pesticide Research Institute, London, Ontario) of a symposium called privately, in February 1961, to discuss the effects of chlorinated hydrocarbons and other chemicals on the ecology of the soil fauna and flora. Dealing with the eelworm problem, Mr F. G W. Jones (Rothamsted Experimental Station) said that a first-class soil nematicide is still awaited Only three—bromomethane, dibromoethane and dichloropropene—have stood the test of time, though some dithiocarbamates show promise He doubted whether soil treatments were the right approach Apart from difficulties of mixing and dispersion, at least 1,000 tons of soil per acre has to be treated Eradication of eelworms is impossible and unnecessary, and he looked forward to a systemic nematicide moving from foliage to roots, suppressing the cyst-hatching factor, and perhaps passing out into the soil to exert a repellant effect Dr Mary Noble (Department of Agriculture for Scotland) considered that seed is not the best launching vehicle for a chemical intended to control soil-borne fungus diseases, while Mr M J Way (Imperial College of Science and Technology) did much to restore a balance in the campaign against insecticidal seed dressings by insisting that the minute quantities used are effective and well placed and do not cause off-flavours in crops, injure beneficial insects or encourage resistance in the pests attacked The problem of deaths of birds after eating dressed seed should be met by more circumspect use of seed dressings and not by restrictive legislation, a view that received much support

The use of systemic insecticides for virus control in potatoes and sugar beet was considered at a second session Hitherto, potato virus diseases have been controlled through crop certification schemes, a method that has become traditional Dr L Broadbent (Glasshouse Crops Research Institute) and others have shown that similar ends may be achieved by using systemic insecticides, though few farmers have yet attempted to take advantage of this With sugar beet there has been no tradition of certification, and farmers responded quickly to a spray-warning scheme begun in 1957 to deal with virus yellows. Dr R Hull

(Rothamsted Experimental Station) disclosed that 95 per cent of the crop was sprayed in 1959 and suggested that spraying had converted 1961 from a 'severe' to a 'marginal' yellows year. Other reports about this disease dealt with the value of menazon and dimethoate as sprays, and with the application of granular formulations of phorate and thiodemeton to the soil or foliage.

In a session on forecasting pest and disease outbreaks great interest was shown in the pioneering work of Mr. G. H. Brenchley (Ministry of Agriculture, Fisheries and Food) on the use of aerial infra-red photography to detect the primary foci of potato blight and to study patterns of its early natural spread. Dr. E. Evans (Fisons Pest Control, Ltd.) reported on difficulties in evaluating materials for blight control and suggested that the performance of copper products and dithiocarbamates differs according to the nature of the epidemic.

Three sittings were devoted respectively to apple mildew, fruit tree pests and the control of *Botrytis* diseases. It was obvious some years ago that apple mildew would again become the problem it now is, and older delegates listening to the seven speakers no doubt recalled similar discussions held thirty years and more ago. In the meantime, mildew has been adequately controlled under a sulphur programme for apples, but it became resurgent as captan and organo-mercury sprays replaced sulphur for scab control and as the renewal system of pruning evolved. Much of the discussion revolved around the difficulty of dealing with continuous conidial inoculum and preventing bud infection, which can evidently be fully accomplished only by weekly or even more frequent application of dinocap or other appropriate fungicides. On fruit tree pests, Dr. G. H. Dicker (East Malling Research Station) and others emphasized the importance of a knowledge of the biology of red spider mite, codling moth and tortrix in the effective timing of fruit tree sprays during the flowering period. No specific methods emerged for dealing with species of *Botrytis*, notably *B. cinerea*, which causes so much destruction to many crops, and the prospect was not made brighter by the ease with which Dr. R. K. S. Wood (Imperial College of Science and Technology) has been able to produce *in vitro* strains of *Botrytis* highly resistant to the fairly effective chlorinated nitrobenzenes. To protect strawberry and raspberry fruits, Dr. W. R. Jarvis (Scottish Horticultural Research Institute) felt that the only real solution would be in a systemic fungicide applied before the flowering stage.

In a session on soil sterilants, Dr. W. Madel (CELA, G.m.b.H.) described experience in Germany with metham-sodium against harmful soil organisms, and Dr. L. P. Flipse (Ligtermoet and Zoon N.V.) showed how valuable this fumigant and herbicide is to Dutch horticulture, particularly in controlling soil-borne fungus diseases of bulbs, carnations and tomatoes. But though practical results continue to accumulate, little is yet known about the mode of action of soil sterilants.

Comment on much of the work discussed at the conference must perforce await publication in the *Proceedings*. Other items included progress reports on a number of new aphicides and acaricides, on the potentialities of organic tin compounds and polybutene formulations, and on special formulations for low-volume spraying. In all the developments outlined it was not difficult to perceive a general desire to find effective chemicals of low mammalian toxicity (if possible, systemic in action) having prolonged effects, and preferably applied in a form that reduces hazards to man, animal and wild-life to the absolute minimum. It was also encouraging to learn from the Laboratory of the Government Chemist of the progress being made in solving the problems which face the analyst examining foodstuffs for pesticide residues.

Speaking as an adviser concerned with the translation of research into practice in Great Britain, Dr. M. Cohen (Ministry of Agriculture, Fisheries and Food) emphasized the difficulty that faces everyone confronted with the vast number of new materials produced during the past fifteen years, and referred to the apparently insoluble problem posed by the confusing combination of endless chemical, common and proprietary names for insecticides and fungicides on the market. Finally, and in an absorbing talk that was delightfully refreshing at the end of three days of "sharing the benefits of new knowledge", Mr. G. Ordish (Department of Technical Co-operation, Tropical Products Institute) dealt with the introduction of insecticides and fungicides into agricultural practice overseas. Little had been said at the conference about economics, though in his view this was perhaps the most important factor of all. In his closing remarks the president mentioned some of the highlights of the discussions and expressed the hope that the conference would be but the first of a biennial series.

W. C. MOORE

THE SOVIET HYDROMETEOROLOGICAL SERVICE

A DECREE, signed by Lenin in June 1921, was the virtual foundation of the modern Soviet Hydrometeorological Service. In a recent issue of *Meteorologiya i Gidrologiya* (No. 6, 1961) the present chief director, A. A. Zolotuhin, traces the history of the Service over the ensuing forty years.

There had been a small meteorological service in Imperial Russia, but owing to foreign and civil war it was in a state of complete decline by 1921. Progress, however, was slow and inadequate during the 'twenties, and by 1929 there were twelve meteorological services in the U.S.S.R. which arose from departments forming their own services, because the main service could not meet their demands. The U.S.S.R. has for long undoubtedly regarded a soundly administered and technically efficient hydrometeorological service as essential to its national economy and to its defence. So in the early 'thirties a unified service was recreated and thereafter progress was rapid. For example, it is claimed that the world's first radiosonde was released in January 1930, and that a network of sounding stations was immediately commenced. By 1941, at the outbreak of War, forty radiosonde stations were in being. Advances in other directions were also substantial.

This was, of course, a period of great expansion for many national meteorological services owing to the development of the science itself and to the increasing demands of military and civil aviation. The U.S.S.R. was clearly no exception.

Since the War, the Hydrometeorological Service has been greatly expanded further. Separate specialist branches have been set up for particular branches of the economy. Emphasis is placed on activities of special importance to the economy of the Union, for example, civil aviation, the hydrology of rivers and watersheds, agricultural meteorology. Nevertheless, the confession is made that the rate of improvement in the accuracy of the forecasts has not really been adequate to satisfy its needs.

Dr. Zolotuhin, however, makes the point that it is the level of scientific research which determines the quality of the service, and there are now a considerable number of meteorological, hydrological and oceanographical research institutions in the U.S.S.R., and the Hydrometeorological Service also has a number of specialist educational establishments for training its staff and potential staff.

From the complete decline of 1921, the past forty years have clearly been years of major expansion, an expansion which indicates the importance attached by the U.S.S.R. to the sciences of meteorology and hydrology. Indeed, with its 29 local and republic directorates and its 20,000 observing points, embracing one-sixth of the Earth's land surface, the Soviet Hydrometeorological Service must now surely be about the largest in the world.

R. F. Zobel

POPULATION TRENDS IN THE U.S.S.R. AND THE UNITED STATES

In terms of population, the Soviet Union and the United States are the third and fourth largest nations in the world. Their combined population of approximately 402 million is close to the population of India, but only slightly more than half that of China. The two nations are alike in many demographic respects. A recent survey entitled "Population Trends in the U.S.S.R.", issued by the Population Reference Bureau, Inc., compares the various population trends in the U.S.S.R. with those in the United States*.

In 1959, the Soviet census counted 209 million people. The birth-rate was 25, the death-rate 7.6 per thousand. In 1959, the United States population was 176 million, and the birth-rate 24.1 and the death-rate 9.4 per thousand. The age-specific death-rates in the U.S.S.R. were higher than those of the United States below age forty, and lower above that age. In both countries, the populations are made up of many ethnic groups, illiteracy is virtually non-existent, and great numbers of people are receiving more education. Only 1.5 per cent of Russians aged 9–49 were reported by the census to be illiterate, but there are urban–rural differences at every school-level. The educational pattern is very different in the two countries.

Migratory trends are similar. With the growth of industrialization, the people of both nations have been on the move, mainly from the agricultural areas to the urban areas. The force which motivates this migration is mainly the desire for advancement.

In 1926, 82 per cent of the population in the U.S.S.R. lived in rural areas and 18 per cent lived in cities. By 1959 the proportion had changed to 52 per cent rural and 48 per cent urban. Russians have been moving east in response to a Government-planned effort to colonize the 'new lands' where industrial complexes have been established.

In contrast, Americans have been going west and mainly into urban areas in a wholly unplanned, casual manner because they desire to live and work there. In 1900, 60 per cent of the population of the United States was rural and 40 per cent was urban. By 1960, the proportion had changed, 37 per cent being rural and 63 per cent urban.

There is a vast difference in the kinds of occupation in the two countries. In 1959, almost 39 per cent of the total labour force in the U.S.S.R. was engaged in agriculture. In 1960 less than 9 per cent of the labour force in the United States was so employed.

NEW SYNTHETIC DETERGENTS

Although the biologically 'soft' detergent which has been developed by the manufacturers, and has been widely distributed in the south of England, has eased the difficulties which have been caused by the discharge of detergent residues to surface waters, the new material does not afford a complete solution to the problems arising from the widespread use of synthetic detergents, and further improvement of this material or the development of new types of surface-active materials is necessary. This is the gist of the Fourth Progress Report of the Standing Technical Committee on Synthetic Detergents*. The new 'soft' detergent, originally supplied to the Luton area, has now been distributed to a large part of southern England, and increased removal of detergents at sewage treatment plants has been observed in many districts. No similar change has taken place in the north, where the type of detergent on sale has not been altered.

One of the difficulties encountered in experimental work on the breakdown of synthetic detergents is the lack of analytical techniques which can be used to study the breakdown products. The analytical methods used are specific for molecules of a given range of size and structure, and it is possible that during sewage treatment some molecules may be only partly degraded or otherwise changed in structure, and may then be undetected in the effluent. It is therefore emphasized in the report that figures given for percentage removal do not necessarily imply that the material has been fully degraded. An extensive programme to be undertaken by various members of the Committee will include investigations of the biological breakdown of single substances, in order to throw light on this part of the problem.

marine bacterial species could be washed and suspended without apparent lysis in a solution of 1 *M* sodium chloride containing no added divalent ions. The quantitative requirements for various solutes for preventing lysis of several marine bacterial species have therefore been determined, and a preliminary report is presented here.

Organisms were grown in a nutrient broth–yeast extract medium containing salts previously established to be required for growth. Cells were collected by centrifugation at 4° C., washed twice in 1 *M* sodium chloride and finally suspended in a volume of the latter such that a 1 : 40 dilution gave about 20 per cent light transmission in a Coleman spectrophotometer equipped with a 655-mμ filter. A 0·25-ml. volume of cell suspension was then added to each of a series of tubes containing solutions of sodium chloride or other solutes to give a final volume of 10 ml.

The results obtained with organism *B*-16, a Gram-negative, polarly flagellated rod, tentatively identified as a species of *Pseudomonas* or *Spirillum*, are given in Fig. 1. Curve 1 shows that there is a small decrease in turbidity of the cell suspension (as indicated by the change in percentage transmission) between 1·0 *M* and 0·2 *M* sodium chloride and a very marked drop below 0·15 *M* sodium chloride. That the drop in turbidity below 0·15 *M* is due to cell lysis is indicated by the fact that turbidity cannot be restored by raising the concentration of sodium chloride. The change in turbidity is thus not merely an optical effect[6]. Furthermore no whole cells can be detected below the 0·15 *M* sodium chloride level by phase contrast microscopy. The same concentrations of lithium chloride and sucrose as sodium chloride and two to three times as much potassium chloride and glucose were also found to be capable of preventing lysis of these cells. The presence of 0·05 *M* magnesium chloride in the suspensions (Fig. 1, curve 2) prevented cell lysis at all concentrations of sodium chloride tested. When the suspensions at the various salt concentrations were centrifuged clear and tested for absorptive capacity at 259 mμ it was found (Fig. 1, curve 3) that the marked decrease in turbidity of the suspensions corresponded to a sharp increase in optical density of the supernatant solutions, indicating the release of nucleic acid material at low salt concentrations. The presence of 0·05 *M* Mg^{2+} in the suspending solutions largely prevented this release (Fig. 1, curve 4).

When the quantitative requirements for divalent cations for preventing cell lysis were examined it was found (Fig. 2) that as little as 0·001 *M* of such ions has a measurable capacity to prevent lysis while above this concentration the turbidity of the suspension was proportional to the concentration of ion added up to about 0·05 *M*. As Fig. 2 shows, Ca^{2+} and Ni^{2+} were more effective than Mg^{2+} in preventing cell lysis, while Mn^{2+} and Co^{2+} activities (not shown) lay between those of the latter. In general the order of activity of the divalent cations in preventing cell lysis appeared to be similar to that of their capacity to form chelate complexes.

Four other marine bacterial species have also been examined: another *Pseudomonas*, a *Flavobacterium* and two strains of *Photobacteria* (kindly made available by Dr. W. D. McElroy). Considerable species variation has been observed both in the capacity of cells to lyse at low sodium chloride concentration and in the ability of divalent cations to prevent it. It is possible to conclude in the case of all species examined, however, that Mg^{2+} and Ca^{2+}, the two divalent ions most prevalent in sea-water at their concentrations in the sea (0·05 *M* and 0·01 *M* respectively), would in all cases reduce and in some cases eliminate the requirement for other solutes such as Na^+ salts for preventing cell lysis. Complete details of these experiments will be published shortly.

Oil Pollution of Marine Organisms

Although much publicity has been given to the harmful effects of oil on bird life, little evidence is available to show how marine organisms are influenced by oil pollution. Recent accidents involving the release of crude oil in Milford Haven afforded an opportunity to commence an assessment of the effects of this substance on the commonest intertidal animals and plants of a rocky coast.

It was found that even when the surface of the water is covered by a thick layer of oil, only a very thin film of oil is deposited on littoral animals and plants as the tide recedes, and much of this is washed off as the tide returns. Oil is, however, deposited at high-tide mark in the form of a band the width of which varies according to the degree of wave action on the shore at the time, and successive high tides may leave a series of bands of oil at slightly different levels. On very sheltered shores, each band may be only a few inches broad but on exposed shores the oil may be spread over several vertical feet of rock face. Clearly, therefore, the intertidal organisms most likely to be affected by oil pollution are those which occur between the lowest high water level of neap tides and the extreme high water level of springs, and include the acorn barnacles, *Elminius modestus*, *Balanus balanoides* and *Chthamalus stellatus*, the limpet, *Patella vulgata*, and on sheltered shores the algae *Fucus spiralis* and *Pelvetia canaliculata*.

Once deposition of crude oil has occurred, the lighter fractions gradually evaporate to leave a tarry residue which seems to be resistant to leaching by rain and moderate wave action. Erosion by water-borne particles (corrasion) probably occurs, but this is likely to be a very slow process except on shores subjected to intense wave action.

Examination of contaminated shores shortly after oil had been deposited showed that those acorn barnacles and limpets the shells of which had been covered by oil appeared to be unharmed and no barnacles were found in which the opercular plates had been glued together by the tarry residues. Examination a fortnight after deposition showed that the amount of oil remaining on surfaces in the immediate vicinity of limpets had been much reduced and that residual patches of oil situated a short distance from these animals exhibited the characteristic imprints of limpet radulas. It appeared likely that these molluscs were continuing to browse over the nearby barnacles and areas of bare rock in order to obtain food, but that in doing so they were inadvertently removing the layer of deposited oil. Since there was no decrease in the limpet population in the contaminated area, it seemed probable that the oil was non-toxic and that it was being passed through the alimentary canal and voided with the other fæcal material.

Some confirmation that limpets are at least partially responsible for removing oil from contaminated shores was obtained during an examination of the latter six months after the accident. All traces of oil had been removed from the areas which support a population of limpets, but on one shore where oil had been deposited to a level above that of the uppermost limpets the tarry residue remained. Examination of barnacles which had been thickly smeared with oil showed that not only had all of it been removed but also that they had suffered no unusual mortality. Plants of *Pelvetia* and *F. spiralis* were also apparently unaffected and had continued to grow at a normal rate.

During the past two or three years, industrial emulsifiers have been increasingly used to clean up oil-polluted shores and they have been found to give effective results on sand and shingle beaches where the amenity value is of importance. Emulsifiers have also been used to clean up contaminated rocky shores, but it has been noticed that their use is followed by a severe mortality in intertidal organisms. Subsequent observations, as yet unpublished, have shown that the type of emulsifier most commonly used destroys all the limpets on a shore and 80–95 per cent of the acorn barnacles, and is extremely toxic to all other forms of intertidal life. It is suggested that in view of the fact that oil films are fairly quickly removed from rocky shores by natural processes, it is both wasteful and unnecessary to use emulsifiers on such shores.

MICROBIOLOGY

Solute Requirements for preventing Lysis of Some Marine Bacteria

Previous work has revealed a specific requirement of a number of marine bacteria for sodium for growth[1,2] and oxidative metabolism[3,4]. For optimum rate and extent of growth, 0·2–0·3 *M* Na^+ was required though limited growth could occur after a sufficiently long incubation period at as low as 0·03 *M* Na^+ (ref. 2). Since sucrose and K^+ exerted only a slight sparing action on the Na^+ requirement of the organisms examined it was concluded that the maintenance of an appropriate osmotic pressure in the medium was by no means the sole, or even the primary, function of Na^+ in the growth of the cells. Nevertheless, cells of many of the species lysed quickly when washed in distilled water, and in the case of one of the species examined in more detail, lysis occurred also when cells were suspended in solutions containing sodium chloride and potassium chloride at concentrations of these salts that were optimum for growth. Lysis, however, did not occur when 0·05 Mg^{2+} or Mn^{2+} was included in the suspending medium[3].

Since Mg^{2+}, and in some cases Ca^{2+} as well, are required for growth by all the species examined[5], the presence of these ions in the growth media used could possibly explain why no apparent osmotic requirements could be demonstrated during growth of the cells. Support for this conclusion was obtained when it was observed that cells of a number of mixed culture and that it was a factor in promoting both growth and nitrogen fixation.

We have also found that treatment with sodium dodecyl sulphate[3] to extract extracellular deoxyribonucleic acid (DNA) resulted in the appearance of DNA in the slime substances. Further experiments to clarify the nature of these phenomena are being performed.

Seasonal Variation in Alginic Acid, Mannitol, Laminarin and Fucoidin in the Brown Alga, *Ecklonia radiata*

The brown alga *Ecklonia radiata* (Ag.) J. Ag. which occurs abundantly in the sub-littoral zone of the southern coasts of Australia, has been found to contain alginic acid, mannitol, laminarin and fucoidin, in conformity with observations on other species of the Laminariales from South Africa and the northern hemisphere. The above constituents were isolated from the seaweed and characterized by physical constants, chromatography and infra-red spectra[1]. An examination has now been made of the seasonal variation in the content of these carbohydrates, which is of interest in connexion with their biochemical function and possible utilization.

Samples were collected at Point Lonsdale, Victoria, each month during December, 1959–January, 1961. Each sample consisted of about twelve plants, which were dissected into laminæ, midrib and stipe. The 'midrib' was taken as that portion of the frond, comprising the elongation of the stipe, from which the 'laminæ' had been removed. The separate portions of the plant were milled through breaker plates in a Bauer defibrator and dried by azeotropic distillation with benzene. They were then ground in a Wiley mill to pass through a 100 mesh/in. sieve, and analysed according to the methods of Cameron, Ross and Percival[2]. In the case of the alginic acid determination, however, much more extensive acid washing was required than suggested by these workers in order to remove calcium ions from the alginate.

The maximum and minimum contents of the various components are shown in Table 1, with their time of occurrence. Marked variations were observed in the contents of laminarin, mannitol and alginic acid, the differences between the maximum and minimum contents decreasing in that order; however, the variations are less than those observed by Black and Dewar[3] for British *Laminaria* species. The fucoidin content is low and less variable relative to the total dry matter. It will be observed also that the contents of laminarin, and to a lesser extent mannitol, decrease from lamina to stipe, whereas the alginic acid content increases.

Table 1. Seasonal Variation in Composition of *E. radiata*

	Maximum			Minimum		
	Lamina	Mid-rib	Stipe	Lamina	Midrib	Stipe
Alginic acid (per cent)*	24·5 April	28·4 April	30·2 April	17·0 September	19·0 September	19·8 September
Mannitol (per cent)*	16·6 February	16·7 April	13·6 June	8·5 July	7·4 August	6·7 October
Laminarin (per cent)*	9·8 May	7·0 May	1·1 May	1·0 August	0·0 August	0·0 August
Fucoidin (per cent)*	1·3 July	1·4 June	1·1 April	0·4 —	0·8 —	0·7 —
Dry matter (per cent)†	22 January	24 June	41 June	17 August	15 August	13 September

* Based on total dry material.
† Based on original wet weight.

Laminarin is regarded by some investigators as a reserve carbohydrate. It is certainly stored in the frond, its content increasing to a maximum in summer and autumn, and decreasing rapidly to zero in mid-winter. The rapid decrease may be associated partly with the shedding of the lamina as well as utilization of reserve carbohydrate. The laminarin content may vary more widely in British species because of a slightly greater range in sea temperatures (45°–57° F. as against 54°–65° F.) and the considerably lower minimum temperature. In the case of laminarin and of alginic acid the seasonal fluctuations are similar for all parts of the plant. However, for mannitol the maximum and minimum contents are reached earlier in the laminæ than in the stipes, which seems to be more in accordance with the behaviour of a reserve carbohydrate than the variations observed for laminarin. The alginic acid content of *E. radiata* appears to be at a minimum in spring, at which time a maximum is reached in the British species.

From the point of view of possible utilization, *E. radiata* should be a useful source of alginic acid and mannitol and may yield appreciable quantities of laminarin, provided that due attention is paid to the seasonal variation.

We wish to thank Mr. K. J. Harrington for helping with the collection and preparation of samples, and Miss Glenys Chong for assistance in their examination.

Occurrence of *Phyllochaetopterus claparedii* McIntosh in the North-east Pacific

The waters near the Friday Harbor Laboratories of the University of Washington have been extensively dredged in recent years. It was of some interest, therefore, that a solitary *Phyllochaetopterus* of relatively large size was brought up from 22 fathoms over a muddy bottom just south of Orcas Island on August 26, 1960, with Forster's anchor dredge[1]. The specimen proved to be identical with the description of *Phyllochaetopterus claparedii* by McIntosh[2] found off Kobe, Japan. It has been recorded since only by Fauvel[3] from Cam Ranh and Tourane Annam (Vietnam). Treadwell's[4] specimens from Porto Rico are only doubtfully attributed to this species. The specimen from Friday Harbor had a pale yellow colour when alive apart from the grey-green gut, and was found in a transparent horny tube about 1 m. in length which was only faintly ringed (not jointed) distally and about 4 mm. across, comparable in size

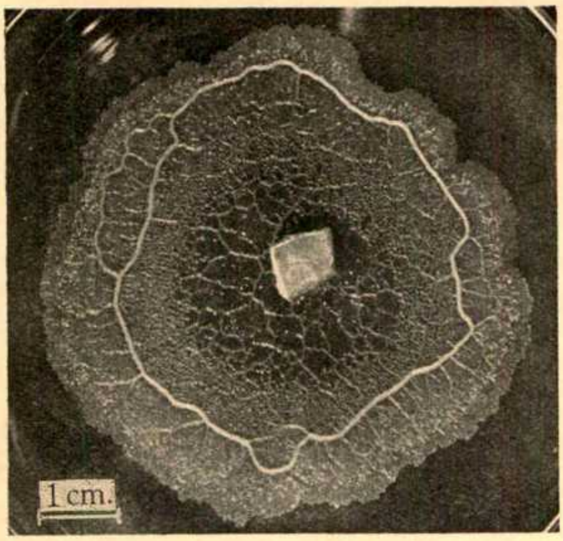

Fig. 1

direction, either clockwise or anti-clockwise. At other times various distributions of streaming in opposite directions in different parts of the main 'vein' are observed. We have observed no systematic correlation between streaming in the main 'vein' and streaming in the branches from it, nor between streaming at any point in the main 'vein' and any other point.

The existence of unidirectional streaming in such a continuous closed circuit, in the absence of any discernible valve- or ratchet-like mechanism, vitiates any hypothesis based on a spatial gradient of physical or chemical factors. On the positive side, this evidence seems to us to offer rather striking support for the notion that the mechanism which generates motive force must be distributed throughout the system and probably arises in the streaming material itself, not merely in the containing walls.

Production of Slime Substance in Mixed Cultures of *Rhodopseudomonas capsulatus* and *Azotobacter vinelandii*

WE have reported[1] that a symbiotic relationship exists between *Rhodopseudomonas capsulatus* (photosynthetic bacteria) and *Azotobacter vinelandii*. When they were mixed, the combination fixed three times more molecular nitrogen than did either pure culture. If the *p*H of the medium were controlled, the nitrogen fixation in the mixed culture was stimulated twelvefold[2].

Microscopically, the cells were surrounded by slime substances produced in the mixed culture after one month, but not observed in the pure culture. It seemed that these slime substances were produced by the interaction between the bacteria. Apparently the substances promoted nitrogen fixation in the mixed culture and also the growth of the mixed culture. Therefore, we extracted the slime substances and investigated them by paper electrophoresis.

van Niel's basal medium (without nitrogen and sodium bicarbonate) was used in this experiment, and 0·3 per cent sodium acetate, 0·2 per cent yeast extract and 0·2 per cent peptone were added to the medium. *R. capsulatus* and *Azotobacter vinelandii*, separately and in combination, were incubated in 3-l. flasks at 27° C. aerobically in the light (10,000 lux). After being cultured for 9 days the bacteria were collected, using a Sharples centrifuge, and washed twice with distilled water. The bacterial cells were stirred with 4 per cent sodium hydroxide solution for 2 hr. and then, after centrifugation, the supernatant was taken. This treatment did not appear to injure the bacterial cells because they remained very active, motile, and capable of good growth. Therefore, it was considered that the 4 per cent sodium hydroxide treatment exerted no effect other than to remove the slime substances from the outside of the cells. The slime substances were dialysed against distilled water at 2° C. for 7 days. The precipitate produced at that time was removed by centrifuging.

Fig. 1 shows the paper electrophoresis of the slime substances. It was found that a peak, labelled '*M*', was observed only in the mixed culture, and not found in either of the pure cultures of *R. capsulatus* and *Azotobacter vinelandii*. The slime substance was positive for ninhydrin, biuret, anthrone reactions and negative for the Benedict reaction. We conclude that the slime substance could be a kind of mucoprotein or mucopolysaccharide, produced specifically in the

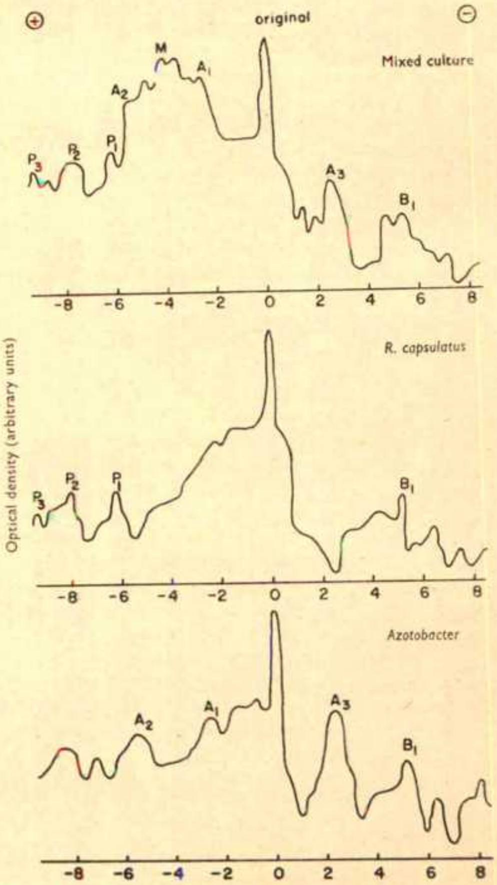

Fig. 1. Electrophoretic patterns of materials extracted from cell walls of *R. capsulatus* and *Azotobacter vinelandii* and their mixed cultures. Conditions: veronal buffer at *p*H 8·6; ionic strength, 0·05; Toyo No. 52 paper; 13 V./cm., 78 m.amp., 5 hr. Absorbancy measured with densitometer (Toyo-roshi Co.)

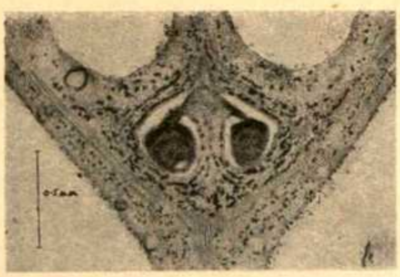

Fig. 1. Vertical section of barren receptacle

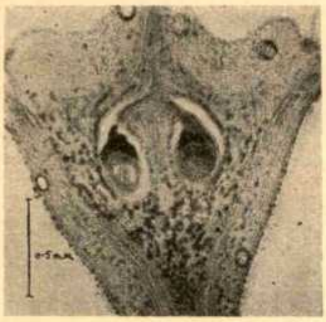

Fig. 2. Vertical section of bearing receptacle

biennial bearing. We have found consistent differences between barren and bearing trees, the flowers of the latter having fewer anthers. Anthers in five buds were counted from each of 30 trees in a random sample which was found to consist of 16 barren and 14 bearing trees. Barren and bearing trees had averages of 103·41 and 52·25 anthers per flower respectively.

Associated with high and low anther numbers were characteristic shapes of the receptacle. Figs. 1 and 2 show comparable sections through newly opened barren and bearing flowers. The former receptacle is seen to be relatively flat due to lack of development of tissue at the base of the style and the ovules are more nearly anatropous.

Flowers of barren trees were found almost always to fall after pollen shedding. Very occasionally one or two berries set but were in our experience invariably one-seeded. There was, however, an additional reason for non-abscission of barren flowers. Infestation by a gall midge (Cecidomyidae) caused destruction of ovules, but at the same time induced an irregular growth of the receptacle. Hitherto the gall midge has only been observed in the larval stage and a complete identification was not possible.

Pimento is a semi-wild crop, and the amount of deliberate planting is negligible. Apart from harvesting the only attention rendered in some groves is the removal of a few barren trees. Under such conditions, if barrenness were a genetic feature such as diœcy, the two types might be expected to approach a one to one ratio with perhaps a slight excess of bearing trees. Table 1 shows a series of samples taken to examine this possibility.

Table 1. FREQUENCY OF BARREN AND BEARING TREES IN SIX RANDOM SAMPLES

Estate	Barren	Bearing	Total	χ^2 P	Remarks
Bengal	14	16	30	0·9–0·8	No barren trees removed
Montpelier	14	16	30	0·9–0·8	Removal of barren trees very infrequent
Grierfield	15	15	30	0·9–0·8	
Greencastle 1	17	13	30	0·7–0·5	A small proportion of barren trees removed annually
2	11	19	30	0·3–0·2	
3	9	21	30	0·05–0·02	
Total	80	100	180		

It was noticed that the barren stigma tended to disintegrate a few hours after flower opening, probably thereby hindering its pollination. Moreover, while it was possible to fertilize bearing plants with pollen from barren trees, inter-fertilization between bearing trees was not obtained. Since examples of the self-fertilization of bearing trees were found it was thought possible that the viability of bearing pollen declined more rapidly. Such a conclusion was supported by a series of pollen-culture experiments.

The present work suggests that pimento although structurally hermaphrodite shows, between barren and bearing trees, quantitative differences in the directions of maleness and femaleness respectively. Such a condition was considered by Darwin[5] to precede the establishment of a complete separation of sexes. It seems probable, therefore, that pimento shows, within the framework of a structurally hermaphrodite flower, an incipient diœcism.

We wish to thank Mr. T. H. Farr, of the Institute of Jamaica, for assistance with the entomological aspect of this work.

Circular Streaming Patterns in a Slime-Mould Plasmodium

IN a previous publication[1], we suggested that the classical 'squeezing from behind' mechanism for protoplasmic streaming is inadequate to explain the actual movements observed in slime-mould plasmodia. As a result of a recent change in culture conditions, remarkably simple and direct evidence to substantiate this suggestion has appeared. Fig. 1 is a photograph of a plasmodium of *Physarum polycephalum* after two days growth at 22° C. in the dark on a particular growth medium. This medium contains, per litre, 20 gm. agar; 5 gm. 'Bacto-tryptone'; 5 gm. dextrose; 0·75 gm. 'Bacto-yeast' extract; 5 mgm. hæmin; 0·8 gm. potassium dihydrogen phosphate; 0·2 gm. disodium hydrogen phosphate; 100 mgm. calcium chloride; 100 mgm. magnesium sulphate; 200 mgm. citric acid; 10 mgm. ferrous chloride; 14 mgm. manganese chloride and 6 mgm. zinc sulphate, adjusted to pH 6·2 and autoclaved for 30 min. at 15 lb./sq. in. (This is modified from the formula kindly supplied to us by Dr. H. P. Eusch, University of Wisconsin.)

The noteworthy feature of this culture is the continuous circular 'vein' which traverses the plasmodium. This feature is observed repeatedly under these culture conditions.

In such a 'vein', all the streaming protoplasm may at times be seen to move continuously in a single

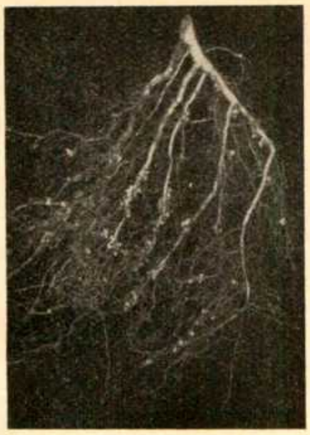

Fig. 2. Nodulation of a molybdenum-deficient alder plant showing many very small nodules uniformly scattered over the entire root system

much higher than in normal plants. Moreover, the same pattern of nodulation has been found in legumes inoculated with ineffective strains of *Rhizobium*.

Œstrogen Content of Plants as a Function of Conditions of Culture

IN the course of a broad investigation on the hormone content of plants, one of us[1], referring to the work of Alexander[2], stressed the important influence that conditions of culture could exert on the amount present in plants of substances having a hormonal action. Preliminary results of our investigation point to a definite influence in this respect.

Carrots cultivated over a period of several years on plots of soil that were left free from fertilizer and farm manure, or were treated either with a mixture of nitrogen, phosphorus and potassium, or with farm manure, were gathered and dried in the air at approximately 60° C., and tested for their œstrogen content, using immature female mice weighing 12–15 gm. The technique used was that described by Simon[3]. It is based on that used by Evans *et al.*[4], with the difference that both the carrot extract, and the diethylstilbœstrol used for the comparison, were given mixed in the diet. The diet was made up as follows: dextrine, 20; linseed meal, 13; barley, 10; wheat, 22; oats, 15; fish meal, 1·5; meat meal, 1·5; yeast, 0·5; mineral mixture, 2; gelatin, 2; dried milk, 12·5.

The food was prepared in the form of a biscuit of 0·5 cm. width.

The mice, divided into groups of six, were fed this diet during a 72-hr. period. They were then killed after 8-hr. fasting. The ovaries, Fallopian tubes and uteri were dissected out up to the cervices, stripped of all extraneous tissues, and weighed.

The findings are recorded in Table 1; they are given in equivalents of the doses of diethylstilbœstrol which served for comparative measurements in the control groups.

Table 1. CONTENT, IN EQUIVALENT OF DIETHYLSTILBŒSTROL, OF CARROTS GROWING ON SOIL CONTAINING VARIOUS FERTILIZERS

Type of fertilizer	Content in equivalent of diethylstilbœstrol (γ/100)	
	Fresh product	Dry product
Control with no fertilizer	0·12–0·16	0·6–0·8
With nitrogen, phosphorus and potassium mixture	0·24–0·26	1·2–1·3
With farm manure	0·40	2

It is readily seen that, depending on the conditions of culture, the titre of œstrogenous substances in carrots can differ by as much as two-fold. Using the same procedure with wheat seeds, our figures were approximately 0·32 γ/100 of dry product of equivalent of diethylstilbœstrol for wheat growing on plots treated with nitrogen, phosphorus and potassium, and about 0·65 γ/100 for wheat growing on plots treated with farm manure.

Incipient Diœcy in Pimento

Pimenta dioica (Linn.) Merrill, known as allspice or pimento, is an important Jamaican crop and the island is the world's chief supplier. Unfortunately, improvement of the crop is hindered by a characteristic type of unfruitfulness among certain trees. The problem has long been recognized and was mentioned by P. Browne[1] in 1755.

The genus *Pimenta* (Myrtaceae) is mono-specific and is of tropical distribution. Its flowers have four sepals and petals, many anthers and an inferior bicarpellary ovary enclosed in a receptacle. The single style is curved, the plane of the curve coinciding with the septum between the carpels. The specific name alluding to diœcy is of Linnæan origin and was based on herbarium material[2]. Preserved specimens of barren plants differ from bearing ones in that the former have a relatively conspicuous development of anthers.

Previous workers have proposed different explanations of barrenness. Grisebach[3] assumed the plant to be diœcious, the barren plants functioning as males. Browne[1], and more recently J. F. Ward[4], on the basis of the hermaphrodite floral structure assumed barrenness was due to some physiological disorder.

The Jamaican Department of Agriculture has had a number of pimento trees under observation for several years, and it is known that barrenness is a property of certain trees and not a transient feature such as stronger effect on *Paramecium caudatum* than on *Trichomonas vaginalis*.

BIOLOGY

Molybdenum and Symbiotic Nitrogen Fixation by Alder (*Alnus glutinosa* Gaertn.)

THE specific effect of molybdenum on the nitrogen fixation by *Azotobacter* spp.[1,2], *Clostridium pasteurianum*[3,4], some blue-green algae (*Nostoc* and *Anabaena*)[5,6] and the symbiotic nitrogen fixation by legumes[7-9] is well established. So far, it is unknown whether molybdenum is also essential for the symbiotic nitrogen fixation of a non-legume such as alder (*Alnus glutinosa*). The aim of the present investigation was to seek such an effect.

The distribution of molybdenum in the different parts of an alder tree growing under natural conditions in a normal acid soil is shown in Table 1. From these observations it will be seen that molybdenum is accumulated in the root nodules. Except the seeds, all other parts show far lower molybdenum-levels. This result points to a molybdenum requirement for symbiotic nitrogen fixation in alder, since the root nodules are the seat of the nitrogen-fixation process.

To obtain more evidence that molybdenum is essential for the symbiotic nitrogen fixation by alder, growth experiments were performed in Neubauer glass jars containing 500 gm. of molybdenum-deficient low-moor peat soil containing ironstone. One set of pots received no treatment except a basic dressing of phosphate and magnesium, whereas a second received in addition 150γ molybdenum per pot. After a growth period of 6 months when the experiment was concluded, the alder plants on the molybdenum-deficient soil showed a pronounced reduction in development as compared with plants growing in the same soil, but with molybdenum added (Fig. 1). The molybdenum-deficient plants had pale-yellow leaves in contrast to the dark green colour of the leaves of plants supplied with molybdenum. In addition, the lower leaves of the molybdenum-deficient plants showed marginal scorch.

Table 1. NITROGEN AND MOLYBDENUM CONTENTS OF DIFFERENT PARTS OF AN ALDER TREE GROWING IN THE FIELD* AT WAGENINGEN (MANSHOLTLAAN), THE NETHERLANDS

Part of plant	Nitrogen percentage in dry matter	Molybdenum p.p.m. in dry matter†
Leaves (young)	3·84	0·25
Stems and branches	0·92 (0·73–1·11)	0·18
Roots	1·76	0·28
Nodules	2·37	1·71
Seeds	3·69	2·10

* The soil was a sandy loam (pH = 5·3) containing approximately 0·2 p.p.m. available molybdenum (*Aspergillus niger* method) (ref. 10).

† Determined chemically with potassium rhodanide, after reduction of any hexavalent molybdenum by stannous chloride.

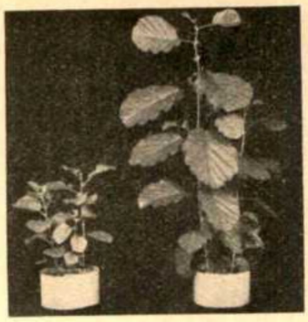

Fig. 1. Effect of added molybdenum on alder plants growing in molybdenum-deficient soil. Left, no molybdenum added; right, 150γ molybdenum as $Na_2MoO_4.2H_2O$ per pot

Obviously, the molybdenum-deficient plants suffered from nitrogen deficiency since yellow leaves and marginal scorch were found to be typical symptoms of nitrogen deficiency in non-nodulated alder plants growing in nitrogen-free molybdenum-containing nutrient solutions. Analyses showed that the molybdenum-deficient plants were considerably lower in nitrogen than those supplied with molybdenum (Table 2). The total amount of nitrogen in the tops of the molybdenum-treated plants was 370 per cent higher than that of control plants.

The molybdenum content of the various tissues of the molybdenum-deficient plants was extremely low (Table 3). Only in the root nodules was an appreciable amount of molybdenum found. The molybdenum-treated plants contained about 10–20 times more molybdenum in their tissues than molybdenum-deficient plants. The root nodules of the plants supplied with molybdenum contained 17·30 p.p.m. molybdenum in the dry matter, a value considerably higher than that known for legumes under comparable conditions[8].

The nodulation of the molybdenum-deficient plants was entirely different from that of plants grown in soil with an adequate molybdenum supply. In the latter plants mostly only one very big nodule (crown-nodule) was formed at the upper part of the root system, whereas in the molybdenum-deficient plants many small root nodules had developed which were uniformly scattered over the entire root system (Fig. 2). A similar effect has been observed by Mulder[9], who found that in molybdenum-deficient clover and lucerne plants the number of nodules was

Table 2. EFFECT OF MOLYBDENUM ON YIELD AND NITROGEN FIXATION BY ALDER PLANTS GROWN IN MOLYBDENUM-DEFICIENT SOIL

	Shoots				
Molybdenum* added (γ per pot)	Mean shoot length (cm.)	Fresh weight (gm. per pot)	Dry matter (gm. per pot)	Total nitrogen in shoots (mgm. per pot)	Nitrogen (percentage increase)

		20	4·32	3·70	4·88	—	+
		22	—	5·28	5·39	3·49	+
		23	5·18	4·43	4·54	3·79	+
		24	5·00	5·15	5·52	3·98	+

* The minimum detectable infections were $\log_{10}$ 2·39 viable units in livers and spleens and 3·49 viable units in intestines.

dosing lesions were present in the mesenteric lymph node of 1 hamster in each of the 2 groups given the higher doses. At 2 months, lesions were seen in 5 of 6 animals given 10^8 units and in all 5 hamsters given 10^9 units. No microscopic lesions were detected in the liver of any hamster.

Since there are already indications in sheep that vaccination may exert a beneficial effect by controlling the initial multiplication of *M. johnei* in the intestinal walls[2], the hamster is likely to prove a suitable experimental animal for the evaluation of vaccines against infection with *M. johnei.*

Behaviour of Protozoa under the Influence of the Synergetic Action of Polyethylene Glycol and Dyes

INVESTIGATIONS on trichomoniasis and the search for a remedy which would effectively destroy *Trichomonas vaginalis* are still being pursued. It has been difficult to find a preparation which is toxic to *Trichomonas vaginalis* and at the same time harmless as regards the vaginal mucous membrane.

Biological examination of the properties of polyethylene glycol showed that it fulfils these requirements[1]. Polyethylene glycol is available in both liquid and solid form depending on its molecular weight. The toxicity of this polymer decreases with increase in its molecular weight. Polyethylene glycol of 1,500–4,000 mol. wt. administered to experimental animals orally and intravenously for 2 years caused no pathological changes[2]. Intravaginal application of the polymer to rabbits did not bring about any deviations from the normal conditions in the vaginal mucous membrane[3]. In 40 hospital patients infected with *Trichomonas vaginalis* treated with the polymer satisfactory results were achieved in about 80 per cent of the cases[4]. The best results are obtained with aqueous solutions in concentrations of 25–50 per cent. For large-scale administration these concentrations are uneconomical. We decided, therefore, to ascertain whether a combination of the polymer with diamond green and gentian violet would not be more effective. It is known that these dyes are to a certain extent toxic in their action on *Trichomonas vaginalis*[5].

The lethal mechanism after administering polyethylene glycol is almost the same for *Paramecium caudatum* as for *Trichomonas vaginalis*. Since it is easy to culture and is very mobile, *Paramecium caudatum* was found to be more suitable for experimental purposes.

All the experiments were carried out as follows: Cultures of *Paramecium caudatum* were placed in a medium of egg-yolk and were used for the experiments when the density of the animals reached approximately 1,000 per 1 ml. of culture. Next, sterile aqueous solutions of polyethylene glycol of mol. weight 4,000, in concentrations of 1, 5, 10, 15, 20, 25 and 30 per cent, were prepared in 4 rows of test-tubes. To each row we added equal parts of:

(1) 0·1 per cent aqueous solution of diamond green
(2) 0·01 ,, ,, ,, ,, ,, ,, ,,
(3) 0·1 ,, ,, ,, ,, ,, gentian violet
(4) 0·01 ,, ,, ,, ,, ,, ,, ,,

By means of a platinum loop, 1 drop of *Paramecium caudatum* culture and 1 drop of the appropriate polyethylene glycol solution with the dye, was placed on a concave glass slide. On mixing the liquids, the time when the *Paramecium* stopped moving was noted. This was taken to be the moment when the animals died, since afterwards they showed no sign of life even when replaced in the culture medium. Each experiment was repeated 5 times from which averages were calculated. Comparisons of these averages are given in Table 1. Investigations with the same solutions were carried out on *Trichomonas vaginalis* at the same time[6]. The results of this experiment are also given in Table 1.

Table 1. TIME REQUIRED FOR *Trichomonas vaginalis* AND *Paramecium caudatum* MOVEMENT TO CEASE AFTER THE ACTION OF POLYETHYLENE GLYCOL WITH GENTIAN VIOLET OR DIAMOND GREEN EXPRESSED IN HUNDREDTHS OF A MINUTE

	Concentration		Concentration of polyethylene glycol (per cent) 30	25	20	15	10	5	1

		0·01	5·56	6·97	8·75	14·05	25·18	32·31	37·00
Paramecium caudatum	gentian violet	0·1	0·18	0·23	0·23	0·24	0·25	0·30	0·30
		0·01	0·34	0·39	0·41	0·54	1·70	2·90	3·18
	diamond green	0·1	0·23	0·25	0·26	0·28	0·29	0·31	0·32
		0·01	0·32	0·34	0·38	0·70	1·50	3·70	4·00

It may be concluded from our experiments that so far as these protozoa are concerned polyethylene glycol and the dyes have a synergetic action. On the grounds of our previous experiments and those described in this communication we consider that polyethylene glycol may be used for treating trichomoniasis. It is a non-toxic compound, cheap, and easy to apply. The addition of the dyes clearly has a more positive effect in the lower concentration of polyethylene glycol (1–20 per cent). This compound has a of 17 and 19 months), the 2 rats in the group treated with normal anti-sub-microsomal fraction sera died as the result of abdominal cancer. It is likely from the size and extension of the tumours that they had first appeared at a much earlier date. At 12 months after cessation of treatment, the rats injected with the 3′-DAB fraction appeared normal and were killed. No significant pathological lesions were found.

The first rat to die had a spherical tumour (3 cm in diameter) adherent to the hilum of the liver with minute white foci throughout the liver. The peritoneum was riddled with small metastatic tumour nodules. The histology of the tumour was that of a typical bile duct carcinoma. Its origin was presumably in a branch of the common bile duct in the liver hilum. The liver itself showed very severe centrilobular necrosis with a cellular reaction and early periportal regeneration, but with many cells in this area still lysing. Some bile ducts in unaffected portal tracts appeared cancerous. The second tumour was quite different. It was very large (6 cm × 5 cm) and sited centrally in the posterior and upper abdominal wall. Its origin was obscure, but at autopsy the possibility of an upper para-aortic lymph node was considered. The whole of the liver surface showed minute yellowish-white foci. The tumour was highly malignant, consisting of large polyhedral cells with no definite acinar formation. Incorporated in it were areas of normal pancreatic glandular tissue. The liver parenchyma in this case was only mildly damaged, but the tumour was invading the liver subcapsular channels extensively. Many cells contained prominent blobs but did not stain for mucus. The nature of the tumour is unknown, but the possibilities include an undifferentiated pancreatic carcinoma and a lymphoid or reticulum cell sarcoma.

If we assume, as there is every reason from long experience with this rat strain, that these tumours were induced and not spontaneous, this result, in spite of the small numbers involved, is highly interesting for the following reasons. They are the first malignant tumours to be produced by the injection of antiserum. A tissue-specific antiserum has in one instance resulted in a tumour of a component of the tissue concerned, which would seem extremely unlikely to be a chance event. Not knowing the nature of the other tumour, there is no point in speculating at this stage on the mechanism of induction, except that it was very probably related to the treatment. Equally important is the fact that the antiserum to the carcinogen-treated liver fraction produced no tumours and no liver damage. There appears to be a striking parallel here with the results obtained by Price[3] at Leeds. She showed that treatment of kidney cells in tissue culture with 3 4-benzopyrene for 10 days rendered them incapable of inducing an antiserum nephrotoxic to mice *in vivo*. The inference was that the tissue-specific antigens had been modified antigenically by the carcinogen. It would appear that the hepatocarcinogen has also modified by haptenic binding the liver tissue-specific antigens and so made the induced antibody innocuous to normal liver.

The normal antiserum produced extensive liver damage in one case, and the process was still continuing at death long after cessation of treatment. There is a possibility here that an auto-immune reaction following liver damage had been established.

This experiment, although now of course being repeated in a larger and more detailed way, would seem to have greater significance, since it was planned on a purely theoretical basis in the hope of achieving the end which, at least in part, resulted. The postulate was that repeated exposure to tissue-specific antiserum would induce adaptive loss of tissue-specific antigens with malignancy as an essential consequence. If the results are repeatable on a larger scale, it would demonstrate beyond doubt that an immunological approach to carcinogenesis is valid, and that the immunological theory of the nature of cancer (see Green[4] for references) may be basically sound.

I am much indebted to Dr. G. M. Bonser for reporting on the tumour sections.

Susceptibility of Hamsters to the Oral Administration of *Mycobacterium johnei*

THE development of a method of counting viable units of bacilli in the tissues of sheep[1] has enabled us to re-examine the potentialities of laboratory animals as experimental hosts for *M. johnei*. The oral route of challenge was chosen because it is the most likely route of infection in naturally occurring Johne's disease. Progressive infection in the tissues after oral dosing was considered to be a better test of the true susceptibility of animals than the direct introduction of bacilli by parenteral methods.

Three groups of twelve hamsters of about 20 gm in weight were dosed orally on one occasion with 10^9, 10^8 and 10^7 viable units of *M. johnei* respectively. The strain of *M. johnei* was the sixth sub-culture from a clinical case of Johne's disease (bovine type) in a sheep. Five or six hamsters from each group were killed at 1 month and at 2 months after dosing. At these times the total viable unit counts were made of the spleen, the liver and the whole of the intestinal walls of each animal. The mesenteric lymph nodes and a piece of liver from each hamster were examined histologically. The results are shown in Table 1.

At 1 month after dosing, infections of the intestines were found in 1 of 6 hamsters given 10^7 viable units, in 3 of 6 given 10^8 units and in 5 of 6 hamsters given 10^9 units.

At 2 months the numbers of animals with intestinal infections were 1 out of 6, 6 out of 6 and 5 out of 5 at the 10^7, 10^8 and 10^9 dose-levels respectively. Where detectable infections were present in the small intestines the mean group counts at the 2-month examination were at least one $\log_{10}$ unit greater than those at the 1-month examination. This shows that progressive infections had been established. Infections were not progressive in the large intestines. *M. johnei* was recovered from the livers or spleens of all the hamsters given 10^8 and 10^9 viable units and examined at 2 months. The viable counts on these tissues were not significantly greater at the second examination compared with those obtained at the first. Whether the infection passed through the intestinal barrier at the time of dosing or as a result of secondary spread from primary progressive foci in the intestine is not yet known. At 1 month after

IMMUNOLOGY

Mast Cell Lytic Antibodies

It is known that mast cell damage by antigen invariably occurs in those circumstances in which an anaphylactic release of histamine is produced in actively sensitized rats[1], mice[2] and guinea pigs[3]. The observation that in passively sensitized guinea pigs the mast cell reaction to antigen was rather uniform and graded with the dose of antibody[4] suggested that the large variation observed in actively sensitized guinea pigs could be due to variation in the relatively small amount of antibodies produced by them. Alternatively, some variation in the quality of the antibody was considered, for example, a difference between precipitating and non-precipitating antibody. However, early work[5,6] showed that precipitating and non-precipitating antibodies were equally efficient for passive sensitizing of guinea pigs.

I was led to the same conclusion by work on the behaviour of guinea pig mast cells in passive anaphylaxis[4]. However, some experiments with rats have suggested that in this species precipitating antibodies are not responsible for the mast cell damage and histamine release occurring in anaphylaxis, but that some other type of antibody might be responsible for these phenomena. For example, while on one hand mast cell damage and histamine release are very much increased in anaphylaxis of pertussis-treated rats[7] which produce very little, if any, precipitating antibodies, on the other both these phenomena may be much reduced in rats sensitized with Freund's adjuvant having considerable amounts of circulating precipitating antibodies. Actually, rats sensitized with Freund's adjuvant seem to be able to produce both types of antibodies since some of these animals present marked mast cell damage and histamine release when challenged with antigen, while others do not. However, this seems to bear no relation to the amount of precipitating antibodies produced by the animal. Thus, there is a difference between the amount of precipitating antibodies produced by immunized rats and the induction of mast cell damage by antigen in anaphylaxis.

Furthermore, I have not succeeded in duplicating mast cell damage and histamine release in anaphylaxis of rats passively sensitized with rabbit or even homologous precipitating antibodies. This occurred also when pertussis-treated rats were passively sensitized and shocked[8]. Therefore, it seems reasonable to conclude that some particular factor or type of antibody is required for the production of mast cell damage in rat anaphylaxis and that the anaphylactic syndrome produced in rats after passive sensitization with rabbit or homologous precipitating antibodies duplicates only that part of anaphylaxis due to precipitating antibodies.

As a working hypothesis we think that rat anaphylaxis is brought about by two different antigen–antibody reactions: (*a*) the reaction of antigen with precipitating antibodies—that do not cause mast cell damage; (*b*) the reaction of antigen with 'mast cell lytic antibodies', which are responsible for the anaphylactic release of histamine. It seems that rats produce normally both types of antibodies and that, depending on the condition of immunization, one of these types of antibody would predominate over the other. Thus, rats sensitized with Freund's adjuvant would produce predominantly precipitating antibodies while rats injected with *B. pertussis* along with the sensitizing dose of antigen would produce predominantly 'mast cell lytic antibodies'. However, the 'mast cell lytic antibodies' would never attain a concentration in the serum adequate to produce passive sensitization. This condition is necessary for explaining the repeated failure of serum taken from pertussis-treated rats to passively sensitize rat tissues either *in vivo* or *in vitro*. Furthermore, since the pharmacologically active substances released from the mast cells cannot account for the severity of anaphylaxis in pertussis-treated rats, one has to consider that the 'mast cell lytic antibodies' are not necessarily specific to these cells but are also very active in causing damage to other cells. Further experimental work is needed on this point.

PATHOLOGY

Apparent Induction of Malignant Tumours by Organ-Specific Antiserum

It was reported[1] that rats injected with 3′-methyl-4-dimethylaminoazobenzene (3′-DAB) showed firm binding of this hepatocarcinogen to the structural lipo-protein complex forming the cytoskeleton, that is, endoplasmic reticulum of the liver cell. The binding here in terms of protein nitrogen was higher than elsewhere. It was shown similarly that firm binding occurred in a sub-microsomal fraction shown by Vogt[2] to contain all, or nearly all, the tissue-specific antigens in the liver cell. This fraction contained the bulk of the phosphatide in the microsomes and was therefore thought to be derived from the endoplasmic reticulum. As with the structural lipo-protein, binding was higher here than in any other cell fraction.

Two rabbits were immunized with 0.1 ml. of the sub-microsomal fraction prepared from the livers of rats injected intraperitoneally 48 hr. previously with 20 mgm. of 3′-DAB in arachis oil and two with a similar fraction from rats injected with arachis oil only. After nine injections (intravenous), the first with 1 ml. of Freund's adjuvant (intramuscular), tube-precipitin tests were erratic in regard to specificity but revealed precipitins to both fractions in all the undiluted sera. Absorption tests indicated that normal liver homogenate absorbed the precipitin from the control but not from the antiserum to the fraction from rats treated with carcinogen.

At this stage, 2-month-old Wistar rats (2 in each group) were injected (intraperitoneally) with pooled rabbit antiserum, absorbed for 1 hr. at 37° C. with normal rat kidney, spleen and lung homogenates, at a dose of 1 ml. spread over 15 injections in 7 months. Immunization of the rabbits providing the sera was continued for the first 9 weeks of this period. At 8 and 10 months after treatment ceased (that is, at the age

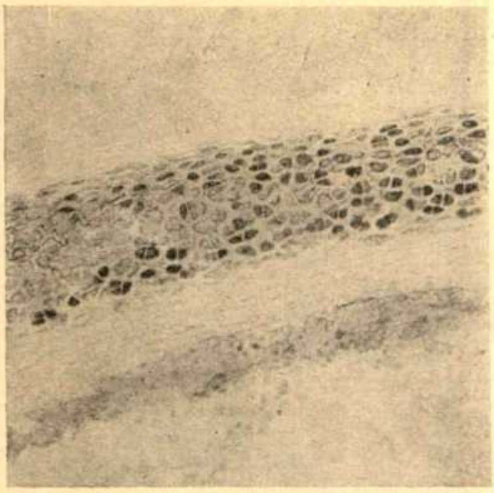

Fig. 1. Rib cartilage of mouse demonstrating marked uridine diphosphoglucose dehydrogenase activity of the subperichondrial cells. Perichondrium and intercostal muscle are negative. Incubation time, 60 min. (× 115)

(Figs. 1, 2). It was considerably reduced or absent in the more mature cartilage cells. The dye was deposited in a finely granular distribution throughout the cytoplasm; the nuclei were consistently negative. The controls, which lacked either substrate or diphosphopyridine nucleotide, were uniformly negative, thus excluding reduction of the ditetrazolium salt via oxidation of endogenous substrates or endogenous reductants. *p*-Chloromercuribenzoate (10^{-4} *M*) completely inhibited the reaction.

The mechanisms involved in the histochemical demonstration of oxidative enzyme activity by use of tetrazolium salts as indicators has been considered elsewhere[4]. In the system under discussion electrons are transferred from uridine diphosphoglucose to the coenzyme via a dehydrogenase and from the reduced coenzyme to the tetrazolium salt by a diaphorase. We are thus demonstrating the activity of a dehydrogenase–diaphorase system, both components of which must be acting to produce a positive result. The reduced tetrazolium salt forms a dark blue granular, insoluble, substantive diformazan at the site of enzyme activity. The rinsing preceding incubation as outlined in the method is important in that it removes endogenous substances capable of reducing the tetrazolium salt independently. We have been unsuccessful in developing a histochemical method to demonstrate this enzyme system in the liver. The extreme diffusibility of some component of the system does not permit the rinsing which excludes or sufficiently minimizes non-specific reduction of the tetrazolium salt, a prominent effect in this organ at *p*H 8·4 (ref. 5). The enzyme in cartilage does not diffuse appreciably and thus is suitable for demonstration by this histochemical technique.

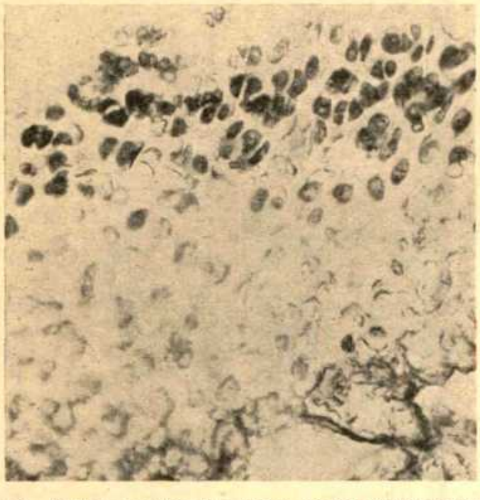

Fig. 2. Higher magnification shows marked intracytoplasmic diformazan deposition in the young chondrocytes (top). Enzyme activity gradually disappears in the deeper lying cartilage cells. Incubation time, 60 min. (× 220)

Glucuronic acid is important in intermediary metabolism, particularly in the conjugating mechanism of the liver (glucuronides), and as a component of mucopolysaccharides throughout the body[1,2]. There is evidence that the glucuronic acid available for these functions is synthesized from glucose via its uridine diphosphoglucose derivative[3,6]. Uridine diphosphoglucose is oxidized through a diphosphopyridine nucleotide-mediated dehydrogenase to uridine diphosphoglucuronic acid. The activity of this system in mammalian liver is well established[3]. Its role in the synthesis of hyaluronic acid in group *A Streptococcus* has been examined[7], and the presence of this system in murine mast cell tumour[8], and epiphyseal cartilage homogenates[9] from young rabbits, has been observed.

The distribution of uridine diphosphoglucose dehydrogenase in cartilage conforms to what we would expect in that it is most active in developing cells at the periphery which are presumably in the process of synthesizing new matrix. These cells would, therefore, require the greatest activity of an enzyme system which produces glucuronic acid for ultimate synthesis into the acid mucopolysaccharides of the matrix. The more mature central cells within well-developed ground substance may no longer require an active production of matrix components and show reduced or absent enzyme activity.

This method therefore demonstrates uridine diphosphoglucose dehydrogenase activity in the cytoplasm of murine cartilage cells from varying body sites. The synthesis of glucuronic acid available for incorporation into mucopolysaccharides probably takes place through the action of this enzyme system. The technique for its demonstration is based on the reduction of a tetrazolium salt.

This investigation was supported by a grant (*C*–3424) from the National Cancer Institute, U.S. Public Health Service.

satisfactory kinetic analysis; (2) the inhibitory effects of various lots of diazonium salts; (3) the low solubility of the azo compounds. The finding that free 'Napthol *AS*' exhibited fluorescence which was abolished by esterification and restored on hydrolysis provided the basis for a simple assay of chymotrypsin. 'Napthol *AS*' fluoresces maximally at 515 mμ when excited at 310 mμ. The excitation maximum coincides with an absorption peak that is absent in the esters. Self-quenching restricts the range of concentration over which fluorescence intensity is linearly related to concentration of the fluor. Fortunately the range of concentration for which the relationship is linear (0·5–15 μ*M*) is appropriate for the assay of enzyme activity.

Crystalline α-chymotrypsin was tested with each of the esters utilizing the fluorescent assay; the phenylproprionoxy ester was hydrolysed at an initial rate 10 times faster than the phenylbutyroxy and 30 times faster than either the benzoxy or phenylacetoxy naphthoic acid anilides. The *p*H optimum of 8·5 for the hydrolysis of the phenylproprionoxy ester agreed with the value obtained using *N*-acetyl tyrosine ethyl ester.

Rat tissues were examined histochemically for the presence of enzymes which would hydrolyse any of the esters. The standard method was to fix tissues in cold neutral buffered formol, washed with gum-acacia sucrose solution[5], and sectioned in the Pearse cryostat. Lipid was removed from the sections with methanol, and the sections incubated in the reaction mixture containing substrate at a concentration of 40 μ*M* in 40 per cent methanol in *tris* buffer at *p*H 8·0. Fast garnet *GBC* was used as the coupler. Sections were incubated 15 and 30 min. at room temperature, and then washed and mounted in polyvinylpyrrolidone[6]. Under these conditions, mast cells were the principal cell type to exhibit enzymatic activity in a variety of tissues examined, including liver, kidney, bone marrow, thymus and myocardium. The mast cell enzyme activity was parallel to that of chymotrypsin; the phenylproprionoxy ester was hydrolysed rapidly, the phenylbutyroxy slowly and the phenylacetoxy and benzoxy esters not demonstrably in the histochemical system. The mast cells from one dog mastocytoma and one cat mastocytoma also contained an enzyme which hydrolysed the phenylproprionoxy derivative.

In rat stomach and intestine, a population of cells distinct from the usual connective tissue mast cells evidenced esterase activity with the phenylproprionoxy and phenylbutyroxy compounds. These cells were usually smaller than connective tissue mast cells, with sparser granules staining less intensely with toluidine blue. Many of these cells appeared in the lamina propria while others were insinuated between epithelial cells of the mucosa in small intestine and colon.

Pancreatic zymogen granules which are known to contain chymotrypsinogen did not hydrolyse the phenylproprionoxy naphthoic acid anilide without prior activation of the enzyme precursor. Sections of pancreas were therefore treated with 0·05 per cent crystalline trypsin at *p*H 6 in the presence of calcium ion for 15–60 min. at room temperature. After trypsin activation, enzyme activity was evident in zymogen granules, in acinar lumina, in intralobular and interlobular ducts. The enzyme in the ducts was better demonstrated when methanol followed activation, whereas staining of enzyme in zymogen granules was greater if methanol preceded activation.

Two types of specificity are demonstrated in this work. There is the specificity of chymotrypsin and the related enzyme of mast cells for the phenylproprionoxy ester of a series of homologous 'Napthol *AS*' derivatives, and there is the restriction of the enzyme hydrolysing the phenylproprionoxy naphthoic acid anilide to connective tissue mast cells, intra-epithelial mast cells of the gastrointestinal tract, and pancreatic zymogen granules and intraductal secretion. The digestive function of pancreatic chymotrypsin is established; the presence of a chymotrypsin-like enzyme in connective tissue mast cells and intra-epithelial mast cells of the gastro-intestinal tract is a contribution of enzyme histochemistry yet to be exploited in work on normal and pathological function.

Histochemical Localization of Uridine Diphosphoglucose Dehydrogenase in Cartilage

THIS communication presents a method for the histochemical demonstration of uridine diphosphoglucose dehydrogenase in cartilage. This enzyme system is active in the pathway of synthesis of glucuronic acid[1,2].

Fifteen young adult albino mice on standard laboratory diet were killed by decapitation, and cartilage from various parts of the body, including larynx, trachea, ribs, joints and epiphyses were immediately removed. Fresh tissue blocks were frozen on dry ice. These were cut in a cryostat (−18° C.) with a rotary microtome at 16μ. The sections were placed on coverslips and rinsed for 5–10 min. in cold (4° C.) 0·1 *M* phosphate buffer at *p*H 8·4. They were then removed to an incubating mixture composed of 5 mgm. of the sodium salt of uridine diphosphoglucose, 2 mgm. diphosphopyridine nucleotide, and 2·5 mgm. of the paranitrophenyl substituted ditetrazolium salt ('Nitro-*BT*') in 5 ml. of 0·1 *M* phosphate buffer at *p*H 8·4. The incubation medium was warmed to 37° C. prior to introduction of the tissues, which were incubated for 30 min.–1 hr. The medium was then drained off and replaced by 10 ml. of 10 per cent neutral formalin at room temperature, in which the tissues were fixed for 1 hr. Sections were then mounted on slides in glycerogel and examined under the microscope.

In each experiment sections were also incubated in solutions which individually excluded substrate or coenzyme to control the specificity of the reaction. *p*-Chloromercuribenzoate (10^{-4} *M*) was used in some experiments as an inhibitor[1,3].

Uridine diphosphoglucose dehydrogenase activity was clearly demonstrated in cartilage cells from the larynx, trachea, ribs, joints and epiphyses. In all instances activity was most prominent in the cartilage cells located at the inner aspect of the perichondrium, and extended for only several cell layers in thickness potentiation was of long duration, often lasting for 30 min or more In this respect there was a difference between the catecholamines and the other smooth muscle stimulants since the effects of adrenaline and noradrenaline rarely exceeded 15 min and were often shorter A few experiments were conducted with substance *P*, which was also found to potentiate the response to hypogastric stimulation when doses of 0 2–0 6 unit/ml were added to the bath

In order to examine the influence of specific inhibitors on the potentiation described, some experiments were performed with atropine Atropine in doses of 0 1–1 μgm /ml abolished the effect of acetylcholine but not those of the catecholamines and histamine

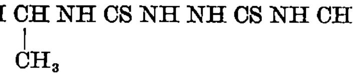
Non-steroid Inhibitors of Pituitary Gonadotrophic Function

WE have obtained striking changes in the reproductive system of animals of certain species treated with some dithiocarbamoylhydrazines (U K patent 878,177) We were prompted to make our experiments by an observation of our colleague, Dr J K Walley

Among the most active of the compounds we examined is 1-α-methylallylthiocarbamoyl-2-methylthiocarbamoylhydrazine (compound 33,828)



$$CH_2{=}\underset{\displaystyle CH_3}{CH}\,CH\,NH\,CS\,NH\,NH\,CS\,NH\,CH_3$$

Administration of this substance to rats of either sex results in selective and reversible inhibition of pituitary gonadotrophic function We have obtained evidence of similar action in dogs and monkeys, but not in mice, guinea pigs, rabbits or horses

This action is manifest in various ways Thus, when female rats with regular œstrus cycles are given daily oral doses of the compound at a level of 20 mgm or more per kgm , cyclic activity, as judged by vaginal smears, ceases within two or three days Smears of the diœstrus type persist for as long as dosing is continued when it is stopped the normal vaginal cycle is resumed within three or four days, even after several months dosing The ovaries lose weight progressively during administration of the compound and, in histological sections, show a decrease in the number of maturing follicles as compared with normally cycling control animals

Table 1 PERCENTAGE REDUCTION IN THE RELATIVE WEIGHT OF THE GONADS AND ACCESSORY ORGANS OF MALE RATS (INITIAL BODY-WEIGHT, *c* 110 GM) GIVEN DAILY ORAL DOSES OF COMPOUND 33,828

Daily dose of compound (mgm /kgm , p o)	Percentage reduction in relative weight					
	After 10 daily doses			After 24 daily doses		
	Seminal vesicles	Ventral prostate	Testes	Seminal vesicles	Ventral prostate	Testes
16	44	21	1	71	61	30
40	66	29	11	88	80	51
100	67	39	6	88	83	55
250	69	49	18	88	85	74

In male rats, daily dosing with the compound at similar levels results in progressive atrophy of the accessory sex glands and a slower loss in weight of the testes The latter change is associated with arrest of spermatogenesis at the stage of early spermatocytes The interstitial cells seem to be unaffected Table 1 shows the percentage reduction in the relative weight of the seminal vesicles, ventral prostate and testes of rats after 10 and 24 daily doses of the compound at various levels, as compared with the relative weight of these organs in control animals of the same age and starting weight Mean figures are given for groups each of six rats having a body-weight of about 110 gm at the start of experiment The treated animals were killed on the day after that on which the last dose was given

The adrenals and thyroid of rats treated with the compound show some increase in relative weight but no histological abnormality In the experiment cited the increase was greatest in the animals given 250 mgm per kgm for 24 days, and then amounted to 37 per cent for the adrenals and 17 per cent for the thyroid

The effect of the compound on pregnancy in the rat depends on the level and duration of dosage and the stage at which it is administered If it is given in sufficient dose (*c* 100 mgm per kgm orally) on any three consecutive days of pregnancy, no litters are obtained This is probably due, if treatment is given in the early stages of pregnancy, to inhibition of implantation, and if in the later stages, to fœtal death and resorption However, in animals given doses insufficient to interrupt pregnancy, the surviving offspring have appeared normal Moreover, the termination of pregnancy in rats by administration of the compound leaves their subsequent fertility unimpaired

Although the effects of the compound on the reproductive system of rats are apparent with daily doses as low as 16 mgm per kgm , daily doses of 350 mgm per kgm are tolerated for up to six months without serious effects on well-being or on the morphology of other internal organs Dosage at levels of 16 mgm per kgm a day and upward does, however, reduce the rate of gain in body-weight and causes, in some rats, patchy loss of hair The acute median lethal dose for rats is of the order of 1 gm per kgm (single oral dose), at which level perforation of the head of the duodenum is often the cause of death

The compound does not affect the increase in weight of the uterus of spayed female rats given œstradiol, nor that of the seminal vesicles or prostate of castrate males given testosterone Atrophic changes produced by its administration in the gonads and accessory organs of sexually mature rats can be prevented by the simultaneous administration of human chorionic gonadotrophin ('Pregnyl'), but the compound does not counteract, in immature animals of either sex, the effects of human chorionic gonadotrophin, pregnant mare serum gonadotrophin ('Gestyl') or human menopausal gonadotrophin These observations suggest that the action of the compound is central rather than peripheral and this is further supported by observations on the pituitary of treated animals Although administration of the compound does not significantly affect the cytology of the pituitary in intact rats, it largely prevents the appearance of castration cells in castrate males, when it is continued from the time of operation until the animals are killed one month later. We therefore conclude, provisionally, that the compound either directly interferes with the production of gonadotrophins by the pituitary, or else affects the presumed hypothalamic control of that function.

Atrophic changes have been detected in the testes and accessory sex organs of dogs given the compound, and in female rhesus monkeys inhibition of menstruation results from its daily administration. We have been unable to obtain any clear evidence of endocrine effects from the compound in mice, guinea pigs, rabbits or horses.

Permeability of the Synovial Membrane to Glycoproteins

ELECTROPHORETIC investigations have indicated differences in glycoprotein pattern between serum and synovial fluid[1-3]. The most marked difference is that the relative amount of α_2-glycoproteins is considerably less in synovial fluid than in serum. It was recently demonstrated[4] that the low α_2-content of rheumatoid arthritic synovial fluid is mainly due to the low concentration of haptoglobin. The synovial fluid–serum ratio for this glycoprotein was significantly lower than for albumin or γ-globulin. The concentration of the small-molecular glycoprotein orosomucoid was, on the other hand, that expected from the total protein content, indicating a varied permeability of the blood-synovial fluid barrier to glycoproteins.

Table 1. SYNOVIAL FLUID – SERUM RATIOS OF VARIOUS PROTEIN FRACTIONS IN CASES WITH AND WITHOUT JOINT DISEASE

Group	No of cases	Vol of synovial fluid (ml.)*	Synovial fluid – serum ratios							
			Glycoproteins			Electrophoretic fractions				
			Haptoglobin	Orosomucoid	Prothrombin-proconvertin	Albumin	α_1	α_2	β	γ
I Cases without joint involvement										
(a) Without evidence of inflammatory disease	5	0.2–0.3	0.03	0.39	0.10	0.43	0.23	0.13	0.23	0.23
(b) With evidence of inflammatory disease (pyelonephritis)	2	0.2–0.3	0.18	0.72	0.27	0.65	0.53	0.35	0.30	0.48
II Osteoarthritis	6	0.5–10	0.24	0.64	0.18	0.46	0.45	0.21	0.32	0.33
III Rheumatoid arthritis										
Untreated	5	10–50	0.38	0.52	0.36	0.57	0.60	0.39	0.51	0.62
After hydrocortisone †	5	2–8	0.18	0.50	0.16	0.58	0.49	0.28	0.42	0.63

* As judged from the amount obtained on puncture.
† Puncture 4 days after intra-articular administration of 50 mgm. hydrocortisone acetate.

Therefore, it appeared of interest to extend the investigations to the glycoprotein permeability of the synovial membrane under normal conditions as well as in other cases with joint effusion. Since it has recently been demonstrated[5] that certain coagulation factors appear to be absent from normal bovine synovial fluid, determinations of the coagulation factors prothrombin and proconvertin, which are known to be glycoproteins, were also included in the present work.

Using previously described methods, synovial fluid-serum ratios for haptoglobin[6], orosomucoid[7], prothrombin and proconvertin[8], and certain electrophoretic protein fractions[3] were determined in cases without evidence of joint disease as well as in cases of osteoarthritis and rheumatoid arthritis. The effect of intra-articular administration of corticosteroids was also studied.

The results are summarized in Table 1. The synovial fluid–serum ratios for haptoglobin and prothrombin–proconvertin are seen to be extremely low in the cases without joint involvement (group I *a*) but increase moderately with increasing degree of synovial inflammation. Following intra-articular administration of hydrocortisone in rheumatoid arthritic cases the ratios for haptoglobin and prothrombin–proconvertin decrease markedly. The ratio for orosomucoid, on the other hand, is seen to be closely similar to that for albumin in the various groups.

The cases of group I *b* (Table 1) deserve special mention. In these cases the synovial fluid was of normal amount and appearance and there was no evidence of joint disease. However, in contrast to the cases collected in group I *a*, the patients of group I *b* presented abnormal serum protein patterns, markedly increased serum-level of haptoglobin and orosomucoid, as well as elevated erythrocyte sedimentation-rate. The changes in the synovial fluid–serum ratios for some of the glycoproteins observed in this group were of a degree found in mild synovitis and may possibly reflect a general change in connective tissue permeability to glycoproteins in infectious conditions.

The results indicate that under normal conditions the synovial membrane is very slightly permeable to certain glycoproteins. This semipermeability is obviously not related to the molecular size of the glycoprotein. Already slight synovial inflammation causes marked changes in glycoprotein permeability, which therefore should be a sensitive index of the degree of inflammation. The mechanism of the selective permeability remains unclarified.

Dietary Citrate and Hypomagnesæmia in the Ruminant

THE sudden onset of clinical hypomagnesæmia in the lactating cow most commonly occurs soon after the change from stall feeding to grazing fresh spring grass, and in the absence of any marked reduction in intake of magnesium. This condition is probably brought about by reduced absorption of magnesium, but the reasons for this are not fully understood. Marked reductions in output of urinary magnesium on changing the diet from hay or grass nuts to fresh grass have been described for sheep[1] in spite of increased intakes of magnesium; this probably indicates reduced absorption. Care[2] recently calculated that a 50 per cent reduction in absorption could lead to the development of hypomagnesæmia within 7 days in sheep.

Mineral balance of herbage[3], low sodium intakes[4], and increased ruminal ammonia production[5] from the appreciable amounts of soluble nitrogenous constituents of spring herbage have all been suggested as precipitating factors, but none of these has been consistently implicated in clinical cases of the disease. In the course of an investigation into the effects of adding organic acids and their salts to the diet of ruminants, we have obtained evidence that dietary citrate levels may be related to the occurrence of hypomagnesæmia.

Eighteen 4–6 month old Ayrshire heifer calves were housed in individual pens and fed 3.5 lb. of a commercial concentrate, 0.5 lb. crushed barley and hay *ad lib.* to a maximum of 4 lb. daily. The calves were paired and allocated at random to treatments providing (*a*) 30 gm. sodium chloride or (*b*) 50 gm. granular sodium citrate in individual daily doses mixed with the barley. Each supplement provided 11.8 gm. sodium per day.

Intakes of food and gains in live weight were similar for both treatments over an 8-week experimental period. In the eighth week, blood samples for the determination of serum calcium, magnesium and inorganic phosphorus were taken on two occasions with the results shown in Table 1. Those calves which had received sodium citrate showed significantly lower levels of serum magnesium and appreciably lower levels of serum inorganic phosphorus than the calves which had received sodium chloride.

Table 1. EFFECTS OF SODIUM CITRATE UPON SERUM CALCIUM, PHOSPHORUS AND MAGNESIUM (MGM./100 ML. SERUM. MEAN OF TWO OBSERVATIONS PER CALF)

Treatment	Magnesium	Calcium	Phosphorus
(*a*) Sodium chloride	2.11	9.47	9.18
(*b*) Sodium citrate	1.86	9.73	8.43
Significant difference ($P = 0.05$)	0.18	0.52	0.79

The results suggest that the ingestion of small quantities of sodium citrate reduce levels in serum of magnesium and possibly inorganic phosphorus. Since skeletal magnesium is more readily available in the young calf than in the adult cow[6] any factor which interferes with magnesium absorption would be expected to take longer to reduce calf serum magnesium significantly.

The daily intake of citric acid (as sodium citrate) amounted to 1.0 per cent of the dietary dry matter; levels of 0.4–0.7 per cent were reported for fresh perennial ryegrass by Hirst and Ramstad[7]. The occurrence of hypomagnesæmia might thus be associated with increased intakes of citrate from herbage. Further experiments are in progress to extend these observations to the lactating cow and to determine more precisely the effect of citrate intake on magnesium metabolism in the ruminant.

Difference in Metabolism of Labelled Thyroxine between Thyrotropic and Adrenotropic Mouse Pituitary Tumours

LITTLE is known about the mechanisms within the pituitary which are involved in the control of thyrotropin secretion exerted by circulating thyroid hormone. In the work reported here mouse pituitary tumours were used to examine this problem since each of these several tumour types reflects quite closely the behaviour of its prototype cell in the normal pituitary. The results suggest there may be a special thyrotropin-secreting cell with an unusual pattern of metabolism for thyroxine. Thus, mouse pituitary thyrotropic tumours were found to contain large amounts of labelled 3,5,3′-triiodothyronine (T_3*) 4 hr. after injection intraperitoneally of labelled thyroxine (T_4*), whereas mouse pituitary adrenotropic tumours and other tissues contained none.

Three strains of thyrotropic tumours in LAF_1 mice, originally made available by Furth[1], were used. Several transplants of an adrenotropic tumour in LAF_1 mice also were furnished by Dr. Furth. A spontaneous fibrosarcoma in LAF_1 mice, kidney, muscle and pituitary from thyroidectomized LAF_1 mice, and a carcinoma of the breast in Swiss mice from Dr. S. Graff were examined as control tissues.

With mouse pituitary tumours, valid conclusions generally may be drawn from groups of 4 mice each (Furth, J., personal communication). Nevertheless, all experiments were repeated for confirmation. Groups of 5 mice each were used for the thyrotropic tumours, and groups of 3 mice each with the other tumours due to a limited number of mice available.

Since two of the three thyrotropic strains grow only in thyroidectomized mice, the thyroid was destroyed in all thyrotropic tumour hosts[2]. The adrenotropic tumours were maintained both in intact and adrenalectomized mice given deoxycortisone subcutaneously once a week.

The biological methods[2] and the methods for extraction of serum[3] used by this laboratory have been detailed elsewhere. Chromatographic separation of the iodinated compounds in tissues was done by the methods of Roche *et al.*[4]. 10–20 μc. T_4* (Abbott) repurified, when necessary, by paper chromatography and containing 0.4–1 μgm. stable T_4, were injected intraperitoneally and autopsy performed 4 hr. later. All tissue samples were rapidly weighed, counted for radioactivity to 5 per cent accuracy in a well-type scintillation counter and then frozen and lyophilized.

After chromatography, further identification of the radioactive compounds was made by two-dimensional

Table 1. PRESENCE OF T_3* IN PAPER CHROMATOGRAMS PREPARED FROM THYROTROPIC MOUSE PITUITARY TUMOURS 4 HR. AFTER INJECTION SYSTEMICALLY OF T_4*, BUT NOT FROM OTHER TUMOURS OR CONTROL TISSUE

‡ Corey, K. D., and Gross, J., *Cancer Res.*, **20**, 476 (1960), have reported formation of radiation iodide from T_4* in experimental mammary tumours.

chromatography, radioautography, and then elution and chromatography of the various radioactive areas.

The results obtained are shown in Table 1. Chromatograms of all three strains of thyrotropic tumours contained T_3* in equal, and high, concentrations, as well as T_4*, iodide and traces of radioactive 3,5,3′,5′-tetraiodothyroacetic acid. The adrenotropic tumours, however, contained no T_3*, and no T_3* was present in control tissues or in serum. A small amount, presumably of 3,3′,5′-triiodothyronine* (reverse T_3*), was demonstrated in chromatograms of serum and of some of the control tissues.

A specific alteration in hormonal environment is required to induce each of the secretory types of experimental mouse pituitary tumour. The resultant tumours are histologically homogeneous and specific. With dependent tumour strains, the same specific end organ hormone is required to suppress growth and hormonal secretion as is normally required to suppress pituitary secretion of the corresponding tropic hormone.

These close similarities to normal pituitary function suggest that each of the secretory pituitary tumours may have originated from corresponding specific anterior pituitary cells and thus reflect their functional behaviour. Ezrin has already postulated[5] from histological evidence that cells secreting thyrotropin and adrenocorticotropin are distinct and can be distinguished from the cells secreting the other hormones of the gland.

Since all three thyrotropic tumours of the present experiment contained a high proportion of T_3* after intraperitoneal injection of T_4* whereas the adrenotropic tumours contained none, the interesting possibility is raised that not only may there be a specific thyrotropin-secreting cell but also that it has a unique metabolic pathway for thyroxine. The formation of large amounts of T_3* could well be related to the inhibitory action which thyroxine exerts on thyrotropin secretion. Unfortunately, both dependent and autonomous thyrotropic tumour strains contained equally high proportions of T_3* and so any relationship to suppression of growth and hence to tumour autonomy or dependency seems to be eliminated.

It is possible that T_4* was metabolized to T_3* elsewhere in the body and was simply concentrated by the thyrotropic tumours. Predilection of the thyrotropic tumour for T_3* as opposed to the adrenotropic tumour would be interesting enough. However, no T_3* was identified in the serum or the various control tissues studied, and T_3* did not accumulate disproportionately in the thyrotropic tumours compared with control tumours and other tissues after T_4* injection[6].

Another possibility, that all pituitary cells deiodinate T_4* to T_3* but lose this system in the formation of adrenotropic tumours, seems unlikely. It is the metabolic behaviour of the thyrotropic tumours which is unique. Similarly, the possibility that the enzyme system responsible for direct diodination to iodide is lost in the thyrotropic tumours so that T_3* is formed alternatively seems excluded by the fact that T_3* is formed by the normal pituitary in about the same relative amounts[8].

PHARMACOLOGY

A Micromethod for the Determination of Bradykininogen in Blood Plasma

BRADYKININOGEN is the inactive precursor from which bradykinin, the hypotensive and smooth-muscle stimulating nonapeptide, can be released by the action of trypsin[1]. The concentration of the precursor in blood can be evaluated by the amount of bradykinin liberated by the action of trypsin on known volumes of plasma. The main difficulty found in a procedure for the determination of bradykininogen is the presence of trypsin inhibitors which interfere with the release of bradykinin, and the presence of enzymes which inactivate it in fresh plasma. This difficulty can be overcome if the plasma is previously heated in boiling water in the presence of diluted acetic acid, in order to obtain a denatured substrate. By this procedure trypsin inhibitors and bradykininolytic enzymes are inactivated[2,3].

After an examination of the conditions for the liberation of maximal amounts of bradykinin, a method for the determination of bradykininogen can be described as follows.

Venous blood is collected in a siliconed syringe moistened with 20 units of an anticoagulant ('Liquemine', Roche) and immediately transferred to a 15-ml. siliconed glass or polyethylene centrifuge tube. The blood is centrifuged and 0.2 ml. of plasma is transferred with a siliconed pipette to an 18 × 150 glass tube containing 1.8 ml. of 0.2 per cent acetic acid. The mixture is heated in a boiling water-bath for 30 min., cooled to room temperature in a tap-water bath, and is then adjusted with N sodium hydroxide (*c.* 0.06 ml.) to pH 7.30–7.80 (Merck Universal indicator paper) and buffered at pH 7 8 with 0 5 ml of 0 2 *M tris* buffer The suspension formed is incubated with 0 2 mgm of crystalline trypsin (Worthing Labs), for 30 min At the end of this period the enzyme in the clear digest is inactivated by adding 5 ml of boiled alcohol After immersion of the tubes for 5 min into a water-bath adjusted at 70° C the liquid is quantitatively transferred to a 125-ml. round-bottom flask and evaporated with reduced pressure to dryness The dry material is suspended in 4 ml of saline and assayed for bradykinin in a guinea pig ileum preparation using the 2 × 2 bioassay described by Rocha e Silva[4]

The bradykinin content does not change significantly if the blood is treated 2–4 hr after collecting or if the dry digest is assayed after keeping it in an evacuated desiccator 12–24 hr

The standard used for comparison was a preparation containing 3 units of bradykinin/mgm , one unit of this preparation was equivalent to 0 5 µgm of synthetic bradykinin (prepared by the Sandoz Labs) according to the procedure of Boissonnas *et al*[5]. One unit of bradykininogen is defined as the amount of the precursor able to liberate one unit of standard bradykinin or 0 5 µgm of synthetic bradykinin

Table 1 shows the concentration of bradykininogen found per ml of blood plasma of man and other mammals measured according to the method described above

Table 1 Bradykininogen (units/ml Plasma)

	Average	Range
Man	21 2	14 8–28 5
Ox	28 9	23 7–33 9
Horse	18 9	17 6–19 7
Sheep	12 7	12 0–13 8
Pig	8 1	5 5–11 6
Dog	12 3	12 0–13 0
Rabbit	20 1	17 5–22 7
Guinea pig	17 7	15 8–20 0
Rat	4 0	2 5– 5 0

Average of determinations made on the plasma of 10 men and 5 women (normals), other species, average of 3 animals

The method described is being used in this laboratory for the examination of conditions expected to alter the bradykininogen content of plasma in several types of experimental shock, surgical conditions and pregnancy

Biological Spectrum of Some New Tuberculostatic 1,3,4-Oxadiazolones with Special Reference to Cross-Resistance and Rates of Emergence of Resistance

THE tuberculostatic activity of 5-(4-pyridyl)-1.3,4-oxadiazolone (*S* 57) has been repeatedly confirmed[1-3], and complete cross-resistance with isonicotinic acid hydrazid (isoniazid) in laboratory tests using *Mycobacterium tuberculosis* is reported by all workers in this field It was, therefore, a little surprising to find that, whereas isoniazid is practically inactive against human leprosy, but active against rat murine leprosy, *S* 57 is highly active against both animal and human leprosy[4-6]

Although isoniazid and *S* 57 show complete cross-resistance in laboratory tests, yet if *H* 37 *Rv* is cultured in the presence of a concentration of isoniazid just sufficient to reduce, but not completely inhibit, growth, and a concentration of *S* 57 one-tenth of that required for growth inhibition, the rate of emergence of resistance to isoniazid is substantially reduced, showing that some difference in the biological spectra of isoniazid and *S* 57 is probably present[7,8] This observation might have some bearing on the unexpected activity of *S* 57 in human leprosy, the more unexpected since it contains, in contrast to most leprostatics, no sulphur in the molecule

The low toxicity and low local irritant properties of *S* 57 led to the extension of the above observations to the salicylate and *p*-amino-salicylate class of substance which shows reduced therapeutic usefulness owing to local irritant properties[9] Conversion of the free carboxy group to the corresponding 1,3,4-oxadiazolones yields compounds possessing similar pharmacological spectra to the original salicylate and *p*-amino-salicylate, but showing, in fact as predicted, reduced toxicity and local irritant action Thus 5-(2′-hydroxyphenyl)-1,3,4-oxadiazolone is an active anti-inflammatory, anti-pyretic and analgesic agent of low irritant properties and toxicity 5-(2′-hydroxy-4′-aminophenyl)-1,3,4-oxadiazolone (*WS* 127) shows a similar tuberculostatic spectrum and order of activity as *p*-amino-salicylic acid, but is considerably more stable chemically Here again complete cross-resistance to various strains of *Mycobacterium tuberculosis* has been observed in laboratory tests using strains resistant to *p*-amino-salicylic acid Yet, on culturing *H* 37 *Rv* in the presence of both *p*-amino-salicylic acid and *WS* 127 at slightly subliminal concentrations the rate of emergence of resistance to both substances is substantially reduced compared with findings obtained using *p*-amino-salicylic acid or *WS* 127 individually on the same strain The same phenomenon has been noted using *p*-amino-salicylic acid and 5-(2′-hydroxy-4′amino-phenyl)-1,3,4-oxadiazol-2-thione

Thus, the laboratory cross-resistance tests commonly used apparently miss some of the finer details of activity, at least in this class of substance, which may be necessary to predict therapeutic effectiveness and rates of emergence of resistance both in animals and man

HÆMATOLOGY

Isolation of an α_2-Globulin from Human Plasma

While examining a method for the isolation of haptoglobin by chromatography on *DEAE* cellulose[1] we noticed that several α_1- and α_2-globulins were adsorbed under the experimental conditions used One of these proteins, an α_2-glycoprotein, has now been obtained at about 90 per cent purity The protein adsorbed together with haptoglobin, cæruloplasmin, cholinesterase and some α_1-globulins at pH 5 0 from human plasma diluted to a freezing point of $-$ 0 15° is the last of these proteins to be eluted at the same pH but with increasing molarity of acetate buffer Indeed, haptoglobin is eluted at 0 1 *M* acetate buffer, cæruloplasmin together with some α_1-globulin at 0 2 *M* and the unknown protein at 0 3–0 4 *M*

When submitted to starch-gel electrophoresis[2], this protein migrates to the α,β-position Protein π, as it may be called, is an α_2-glycoprotein containing about 10 per cent hexoses Protein π is different from these three well-known α_2-globulins haptoglobin, cæruloplasmin and α_2-macroglobulin It differs from haptoglobin by its electrophoretic mobility on starch-gel, showing but a single band in the α,β-position (Fig. 1) and a somewhat faster migration on paper strip Protein π has no hæmoglobin-binding capacity and no immunological relationships with haptoglobin The new protein is precipitated by rivanol at pH 7, whereas haptoglobin is not The protein under consideration differs from cæruloplasmin in its position on starch-gel at pH 8 6 It is colourless and contains no copper and shows no oxidase activity There is no immunological relationship with ceruloplasmin as studied by the Ouchterlony technique and immunoelectrophoresis Finally, there is no immunological relationship between α_2-macroglobulin and protein π and again the position on starch-gel of the two proteins is quite different

The protein separated by chromatography on *DEAE* from whole plasma contains zinc in various amounts Work is in progress to establish whether zinc is a definite part of the native protein, or a fortuitous contaminant Protein π has been isolated under the same experimental conditions from fraction III as obtained during routine fractionation of human plasma following a slightly modified Nitschmann technique[3] Whole plasma contains about 0 2 gm /l of this protein and some total anti-human-serum gives a precipitation line with the purified protein A screening for specific enzymatic or clotting activity has not yet given a positive result

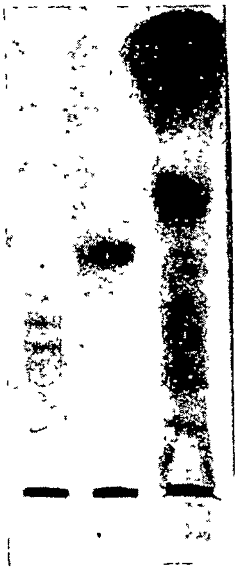

Fig 1 Position on starch-gel of protein π (in the centre), whole plasma (right), isolated haptoglobin (left)

Quantitative Sub-Groups of the *B* Antigen in Man and their Occurrence in Three Racial Groups

Numerous authors[1–5] have described rare variants of the *B* blood group antigen which may differ qualitatively from other *B* antigens Formaggio[6] concluded from his examination of 250 samples of *B* agglutinogens that differences within the *B* group were quantitative rather than qualitative During the performance of 50 per cent end-point hæmagglutination assays of the *B*-anti-*B* system[7], it was noted that *B* cells from a Negroid individual were more strongly agglutinated than were those of Caucasoid origin The probability–log assay curves in Fig 1 show the difference observed with four doubling dilutions of anti-*B* serum in an equilibrium system with equal numbers of the two types of *B* cells of equal freshness The percentages of cells agglutinated were obtained by the free-cell counting technique described in an earlier paper[8] and are plotted against the logarithms of the antiserum concentrations Since the parallel assay curves indicated that these agglutinogens differed quantitatively rather than quali-

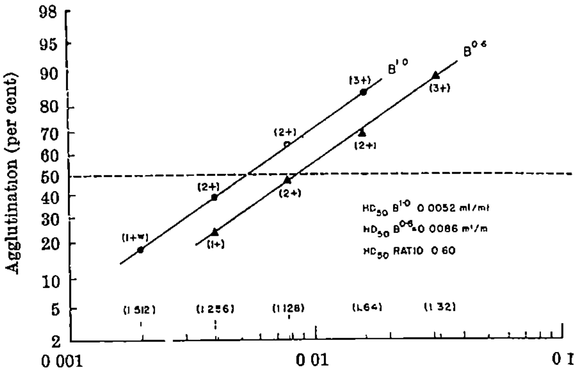

Fig 1 Hæmagglutination assay curves of red cells of two sub-groups of the *B* antigen.

The degree of gross agglutination is indicated in parentheses 3+, Large visible clumps of cells with only a few free cells, 2+, macroscopically many small clumps with more free cells, 1+, macroscopically no visible agglutination, microscopically many small clumps of 4–8 cells, 1+*w*, no visible agglutination macroscopically, microscopically small clumps of 2–4 cells

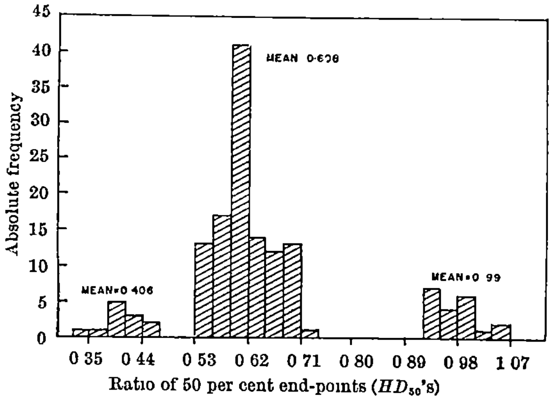

Fig 2 Distribution of HD_{50} ratios for red cells of 143 blood group B individuals

tatively, the relative 'strength' of the B cells could be ascertained from the 50 per cent hæmagglutination end-points or HD_{50}'s interpolated from the assay curves A ratio of the HD_{50}'s showed that the Caucasoid cell possessed only 60 per cent of the agglutinating strength of the Negroid cell This difference was observed with numerous samples from these same individuals over a period of two years, and thus appears to be an intrinsic property of the agglutinogen from a given individual The stronger cell was tentatively assigned a value of unity and provisionally designated $B^{1\cdot0}$ while the weaker Caucasoid cell was termed $B^{0\cdot6}$ to avoid confusion with the terminology B_{100}, B_{80}, B_{60}, etc , proposed by Hirszfeld[9,10] for the B_c (complete) antigen and its transition forms

In order to determine whether quantitative subtypes vary in ethnic groups, samples of group B blood from Caucasian, Negro and Mongolian individuals were collected in equal volumes of modified Alsever's solution at the Washington Red Cross Blood Donor Center The cells were compared with a standard $B^{1\cdot0}$ cell on the day of collection by the assay method Concentrations of standard and unknown test cells were carefully adjusted to 26,000 ± 800 cells/mm^3 by means of the Coulter counter. The frequency distribution of the HD_{50} ratio values for a population of 143 individuals of blood group B is shown in Fig 2 It is evident that a segregation into three distinct populations ('percentage grades') was possible The group of 12 samples which were more weakly reactive than the $B^{0\cdot6}$ group has been designated $B^{0\cdot4}$ since they exhibited approximately 40 per cent the agglutinability of the standard cell The results of the testing of 100 Caucasoid, 25 Negroid and 18 Mongoloid B antigens are presented in Table 1 It is noted that $B^{1\cdot0}$ occurs in half the American Negro population but in only 9 per cent of Caucasians and in none of the Mongolians The $B^{0\cdot6}$ predominates in Caucasians and Mongolians while $B^{0\cdot4}$ appears to be in highest frequency among Mongolian peoples The fact that the results do not accord with the distribution expected of homozygotes (BB) and heterozygotes (BO) suggests that the observed differences are not related to the ABO genotype of the individual In support of this, it was found that samples from one individual whose most probable genotype is BB as evidenced by family studies of three generations, and three from known BO individuals, fell within the same percentage grade ($B^{0\cdot6}$). Subjects were not available for examination of the heredity of these antigens, however, it is reasonable to assume that they are expressions of multiple allelomorphs at the B locus These sub-groups may, indeed, correspond to the pleiades B_m, B_r, B_j described by Hirszfeld and Amzel[10] On the other hand, $B^{1\cdot0}$ may be an exclusive character of the Negroid race since it is possible that the nine Caucasoid $B^{1\cdot0}$ antigens encountered are the result of race crossing Whether $B^{1\cdot0}$ is an exclusive Negroid character or occurs in all races in different frequencies can only be resolved by testing pure racial populations.

Table 1 Distribution of B Antigens in Three Racial Groups

Racial group	Types of B antigen $B^{1\cdot0}$	 $B^{0\cdot6}$	 $B^{0\cdot4}$
Caucasoid	8	87	9
Negroid	12	13	0
Mongoloid	0	15	3

A Correlation between Surface Charge and Coagulant Action of Phospholipids

The property of water-insoluble amphipathic molecules to alter the electrokinetic charge of lipids has been exploited by Bangham and Dawson[1] in elucidating the charge requirements of certain enzyme/substrate interactions Their results show clearly the interdependence of both sign—positive or negative—and magnitude of enzyme and substrate interaction in any particular ionic environment Whereas variation of pH, uni- or di-valent ion concentrations may affect the charge on both enzyme and substrate simultaneously, the addition of a water-insoluble amphipathic molecule to the lipid ensured an alteration of the substrate exclusively

In the light of this experience and of the apparent anomalies in the ability of various phospholipid emulsions to accelerate the clotting of plasma[2-4], an attempt has been made to correlate the ζ potential of lecithin/amphipathic molecule mixtures with their effects on the clotting reaction promoted in plasma by Russel viper venom

To 1 5 µmole-aliquots of ovo-lecithin in chloroform (isolated from mixed egg phospholipids by chromatography on alumina and silicic acid columns) were added progressive volumes of synthetic di-cetyl-phosphoric acid (0 66 µmole/ml) in chloroform Each mixture was taken to dryness *in vacuo* and emulsified in 1 0 ml of a 0 045 *M tris* buffer in 0 1 *M* sodium chloride Electrophoietic mobilities of the emulsion particles were measured by direct observation in a horizontal microelectrophoresis cell of the type described by Bangham, Flemans, Heard and Seaman[5] The clotting system utilized fasting human plasma, obtained by centrifuging citrated blood

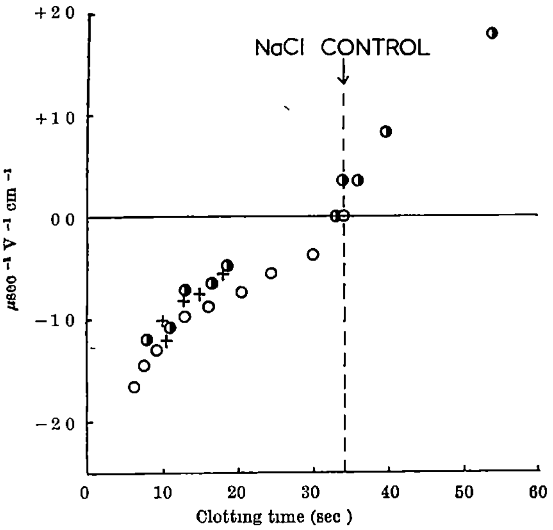

Fig 1 Curves to show relationships between clotting time and electrophoretic mobility, positive or negative, of various lecithin mixtures Mobilities were carried out in 0 045 *M tris* in 0 1 *M* sodium chloride at *p*H 7 2 Clotting times represent means of three measurements

○—○, 0 16 μmole lecithin plus varying amounts of dicetyl phosphoric acid, ◐—◐, 0 16 μmole lecithin plus 0 045 μ*M* dicetyl phosphoric acid to which is added varying concentrations of C_{22}-pyridinium bromide, ×—×, 0 16 μmole lecithin plus varying concentrations of phosphatidyl ethanolamine

first at 3,000 r p m for 10 min and then at 20,000 r p m for 15 min To 0 1 ml of such plasma were added 0 1 ml of the mixed phospholipid emulsion, 0 1 ml of 1 100,000 'Stypven' brand (Burroughs Wellcome and Co) Russel viper venom in water and finally 0 1 ml 0 025 *M* calcium chloride All reactants were maintained at 37° C and the clotting reactions were followed at this same temperature

Fig 1 shows the relationship between the electrophoretic mobilities of the various lecithin/dicetyl phosphoric acid mixtures added to plasma and the observed clotting times It can be seen that as the negative charge on the suspension increases, its ability to accelerate the clotting induced in plasma by Russel viper venon also increases

The suspension promoting the most rapid clotting has a mobility of 1 6 sec $^{-1}$ volt^{-1} cm $^{-1}$ This agrees remarkably closely with the value for the particles present in the brain extract described by Bell and Alton[6] (Table 1) Lecithin/phosphatidyl ethanolamine mixtures are also negatively charged (due to the partial ionization of the amine group at *p*H 7 2) and the mobility/clotting time relationships coincide with those of lecithin/dicetyl phosphoric acid mixtures (Table 1 and Fig 1)

That the surface charge is, in all probability, intimately concerned in the reaction is emphasized by the observation that progressive neutralization of the negative charge of the suspension by the addition of C_{22}-pyridinium bromide to the lipid mixture results in a proportionately decreased effectiveness as evidenced by the prolongation of clotting time (Fig 1) Addition of excess C_{22}-pyridinium bromide yields a positively charged lecithin/dicetyl phosphoric acid suspension causing an extended clotting time This latter observation, too, holds important implications for the possible role of orientated surfaces in the whole process of blood clotting

Table 1 COMPARISON OF VARIOUS PHOSPHOLIPID MIXTURES AND THEIR COAGULANT ACTION

Phospholipid mixture	Mobility (μsec $^{-1}$ volt^{-1} cm $^{-1}$)	'Stypven time' (sec) av of 3 readings
Tris/saline control	0	24
0 163 μmole lecithin	Iso-electric	24
0 115 μmole lecithin + 0 035 μmole dicetyl phosphoric acid	−1 6	7 0
0 034 μmole lecithin + 0 120 μmole phosphatidyl ethanolamine	−1 04	8 0
Brain phospholipids, Bell and Alton (ref 6)	−1 69	7 9
Platelets	−1 2	8 7
0 163 μmole lecithin + 0 05 μmole dicetylphosphoric acid + 0 08 μmole C_{22}-pyridinium bromide	+1 8	34 0

The effects on clotting time of other amphipathic molecules having alternative anions, for example, fatty acids, are at present under investigation However, in view of the slightly different affinities of calcium ions for phosphate as compared with carboxyl anions, it is quite probable that the optimum mobilities of suspensions activated by fatty acid, in *tris*-buffered saline, may be different from those reported in Table 1

Final appraisal of the relationships between the surface charge of orientated phospholipids and their possible catalytic role in enhancing blood clotting must await measurement of clotting time in the presence of a constant surface area of test lipid

HISTOCHEMISTRY

Histochemical Examinations of Chymotrypsin-like Esterases

IN 1953 Gomori[1] discovered a tissue enzyme which hydrolysed chloracetoxy naphthoic acid anilide Mast cells were found to have a large amount of this enzyme activity Based on the demonstration that the time required to achieve a given colour intensity in an enzymatic histochemical system is inversely proportional to enzyme activity[2], it was estimated that mast cells had 30 times the activity of liver and five times the activity of neutrophiles Later, Benditt and Arase[3] were able to show that the enzyme in mast cells strikingly resembled bovine α-chymotrypsin The present work has carried the resemblance further and examined the distribution of the enzyme in the rat, utilizing a newly synthesized series of esters of naphthoic acid anilide ('Napthol *AS*')

The presence of a phenyl group in the acidic portion of an ester is an established character of specific chymotrypsin substrates[4]. Esters of 'Napthol *AS*' were therefore synthesized beginning with the benzoxy ester and sequentially adding a methylene group between the carboxyl carbon and the phenyl ring, giving the phenylacetoxy, phenyl proprionoxy and phenylbutyroxy esters

The use of diazo coupling with the free naphthol released by hydrolysis to measure enzyme activity in the test-tube was unsatisfactory because of (1) the relatively slow coupling which precluded tion, based on the efflux of sodium, increases the sodium uptake to 33 pmoles/cm.^{2}/stimulus. By direct recording, each 4-sec. stimulus was found to elicit, on the average, 4–5 repetitively produced spikes. Thus, the sodium uptake per spike is 7–8 pmoles/cm.^{2}. Using the highest value for the spike in uterine smooth muscle of 73 mV.[5] it can be readily shown that movement of this amount of sodium is capable of discharging a membrane capacity of 9–11 μF./cm.^{2}, a value which closely resembles that of other vertebrate excitable membranes. On the other hand, if the membrane capacity of the rabbit myometrial cell is assumed to be the same as that of frog sartorius muscle fibre or that of sheep Purkinje fibre[6], the observed and estimated amount of sodium moved could cause a change of membrane potential of about 70 mV. Thus, even without correcting for diffusion delay, which is appreciable in this tissue, the results strongly suggest that the ionic hypothesis of excitation can be applied to the rabbit myometrium.

The half-time of extracellular elution of sodium-22 is 10·3 ± 0·71 min. (mean ± *S.E.* of 22 preparations). From this and the thickness of the preparations the diffusion constant of sodium was calculated to be $0{\cdot}202 \times 10^{-6}$ to $1{\cdot}16 \times 10^{-6}$ cm.^{2}/sec. At the maximum, this is one-fifth the value in frog sartorius muscle[7]. The slow extracellular diffusion together with a higher intracellular sodium concentration[8] could conceivably allow local accumulations of sodium even when the entire preparation is immersed in sodium-deficient media. Probably such an explanation can account for the observation that action potentials in smooth muscles seem to be independent of the external sodium concentration.

This work was supported in part by a grant (*A*–1713) from the National Institutes of Health, U.S. Department of Health, Education and Welfare. Support for one of us (D. Z.) was derived from funds allotted by the U.S. Public Health Service and the National Science Foundation.

Effect of Some Smooth Muscle Stimulants on the Motor Response of the Isolated Guinea Pig Vas Deferens to Hypogastric Nerve Stimulation

RECENTLY potentiation of the response of the cat nictitating membrane to sympathetic nerve stimulation has been shown to occur with serotonin[1] and substance *P* (ref. 2). Burn and Rand[3] have found that circulating noradrenaline increases the responses of organs to sympathetic stimulation.

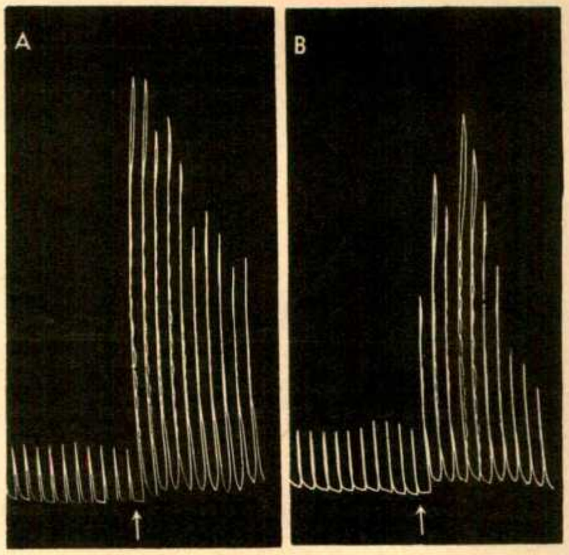

Fig. 1. Contractions of the isolated guinea pig vas deferens in response to hypogastric nerve stimulation (10 V., 2 msec., 5 pulses/sec.) for 5 sec. at 2-min. intervals; bath volume 50 ml. *A*, At arrow, addition of 0·01 μgm. acetylcholine; *B*, at arrow, addition of 5 μgm. adrenaline

Some results are presented here showing that other smooth-muscle stimulants can modify the motor response to nerve stimulation of sympathetically innervated smooth muscular organs. The vas deferens was chosen because this organ is stimulated by most of the smooth muscular stimulants occurring in the body.

The vas deferens with the hypogastric nerve was prepared according to the method described by Huković[4]. The organ was placed in a 50-ml. bath containing Tyrode solution at 37° C. and aerated with oxygen. The contractions were recorded with a frontal writing lever on a smoked drum. The hypogastric nerve was placed on stimulating electrodes and immersed in liquid paraffin. The nerve was stimulated every 1 or 2 min. for 5–10 sec. with a stimulation of supramaximal strength (8–15 V.) and a duration of 2 msec., the frequency being in the range 5–20 per sec. The responses remained for at least 5–6 hr.

Contractions of the isolated guinea pig vas deferens could be elicited by addition to the bath fluid of adrenaline, noradrenaline, acetylcholine, histamine and serotonin although the concentrations required were rather high. Concentrations of at least 5–10 μgm./ml. of adrenaline and noradrenaline had to be used to obtain a moderate contraction. The effective dose of acetylcholine was lower (1–10 μgm./ml.) and those of histamine and serotonin were higher (10–80 μgm./ml.). In general these substances could be ranked in the following order: acetylcholine > adrenaline > noradrenaline > histamine > serotonin.

It was observed, however, that doses of smooth muscular stimulants, which were too small to induce contractions of the isolated vas deferens, caused a conspicuous potentiation of the motor response of the organ to nerve stimulation. Doses ten to a thousand times smaller than those required for eliciting a moderate contraction of the organ increased the response to nerve stimulation two or three times or even more without any gross changes in the basal tone of the ductus. The ability for potentiation followed the same order as that for stimulation. The

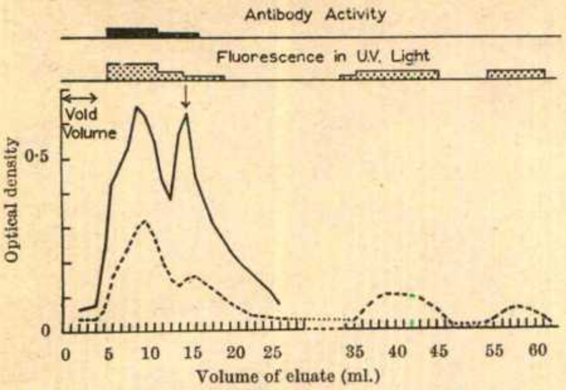

Fig. 1. Elution diagram for an 8-ml. volume of γ-globulin fraction of rabbit anti-human γ-globulin labelled with fluorescein isothiocyanate. The column of 'Sephadex *G*-25', 11 cm. × 0·6 cm. diameter, at room temperature, was eluted with phosphate saline buffer *p*H 7·4. Millilitre eluates were collected. Maximal fluorescence and antibody activity corresponded to eluates of maximal protein and dye absorption. Absorption at 280 mμ, ——; absorption at 490 mμ (dye), - - -

Examination in agar-gel diffusion plates (Fig. 2) shows sharp limitation of antibody activity to the volume of eluate corresponding to the volume of original protein solution and to that giving maximal absorption at 280 mμ (that is, little or no dilution of antibody activity). This was confirmed by the finding that negligible alteration in antibody titre occurred in the eluates. Protein recoveries of up to 95 per cent were obtained in volumes of eluate equivalent to the original volume of the conjugate.

Apart from the use described here, cross-linked dextran gels can also be profitably used for the concentration of fluorescent antibody activity where this is weak, using the method suggested by Flodin, Gelotte and Porath[8] for concentrating solutes of high molecular weight.

Purification of dye-protein conjugates by this method appears to be quicker, simpler and more efficient than other methods[9] at present in use.

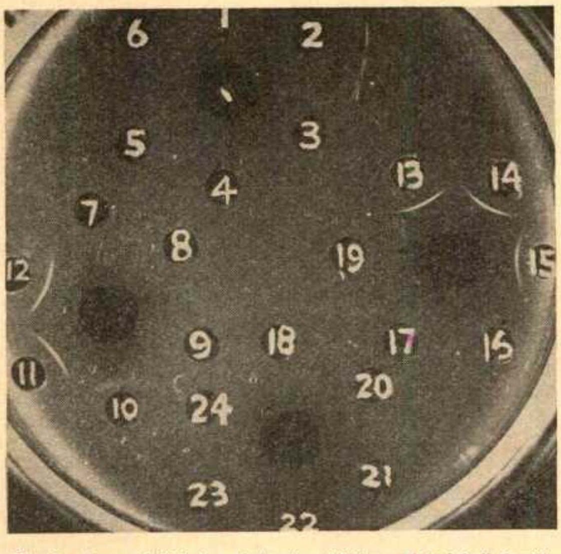

Fig. 2. Agar gel diffusion plate of anti-β-lipoprotein labelled with fluorescein isothiocyanate against β-lipoprotein. After eluting from the column of 'Sephadex *G*–25', samples were taken from each of the ml. eluates and put up against β-lipoprotein. Holes 1–9, representing the void volume of the column, show no precipitation, whereas holes 10–16, representing the volume of protein solution originally put on column, show precipitation. Holes 17–24 show no precipitation

PHYSIOLOGY

Sodium Influx and Excitation in Uterine Smooth Muscle

The applicability of the ionic hypothesis of excitation, more specifically the transient increase of sodium permeability during an action potential[1], has not been extended to smooth muscles in general. This is due largely to serious technical difficulties in impaling the small cells of smooth muscles, as shown by the comparatively low and widely variable values of membrane potentials for smooth muscles. Direct tests of the effect of sodium deprivation on the action potential are therefore rather difficult to make. Additional confusion has been caused by claims that action potentials persist in media containing very little sodium[2] or no sodium at all[3].

An alternative approach to test the applicability of the ionic hypothesis to smooth muscle is to determine the sodium influx associated with each impulse to see whether the charge carried by the sodium ions moving across the excitable membrane can account quantitatively for the displacement of the membrane potential occurring during an action potential. This approach has been used in paired comparisons on isolated myometrial strips from œstrogen-dominated uteri of rabbits. The strips were incubated in a sodium-22 containing Krebs's bicarbonate solution. One of the pair was left unstimulated, and at the incubating temperature of 24° C. spontaneous activity was infrequent. The other of the pair was stimulated in end-to-end fashion by 4-sec. long, 60-c./s. a.c. stimuli, once every minute for about 2 hr. When the relative amounts of sodium-22 eluted from the muscles were plotted against time, the resulting curves could be fitted by exponential equations with two terms. From the intercept values and the rate constants of both terms, the total intracellular sodium-22 at the beginning of the elution was calculated according to the method discussed by Huxley[4].

In paired comparisons of muscle strips allowed to recover for 3 hr. before being loaded with sodium-22 the extra uptake of sodium due to applied stimulation was 16·3 pmoles/cm.^{2}/4 sec. stimulus (mean of 6 pairs, with total stimuli of 120, *S.E.* ± 3·06). Since the stimuli were applied once every minute, allowance must be made for the sodium that entered the cell but was then extruded between stimuli. This correc-

98 per cent of the salts and only 10–15 per cent of the activity are lost during dialysis But as only small quantities of lysozyme are involved in the preparation it was necessary to eliminate all the salts without any further loss of activity This is obtained by filtration on 'Sephadex *G*–50' column 50 × 1 2 cm. (buffer, pyridine 0 3 *M*, HAc 0 1 *M*; *p*H 5 5) (Fig. 2).

Chromatographically pure lysozyme from human milk After re-chromatography on carboxymethylcellulose, the lysozyme from human milk is obtained with a constant specific activity Furthermore, no increase of the purity was observed after filtration on 'Sephadex *G*–50' The fact that the lysozyme obtained in this way is chromatographically pure has been again verified by submitting the enzyme to a ion-exchange (partition) chromatography on 'Amberlite *CG*–50' The lytic enzyme can be chromatographed on a 20 × 0 9 cm. column buffered with a 0 2 *M* phosphate buffer of *p*H 7 0, without any change of the *p*H, the molarity or the temperature of the buffer during the chromatography (elution after 50 ml)

Some properties of the lysozyme The lysozyme from human milk, as all previously examined lysozymes[1], is very stable at acid *p*H it resists to 100° C for 3 min at *p*H 4 5 without any significant loss of activity, it is, however, unstable at alkaline *p*H at *p*H 7 5 a loss of 30 per cent of the activity occurs after 1 min at 100° C If the specific activity is by definition 1 for hen's egg white lysozyme, it is about 2 for human milk lysozyme The molecular weight is approximately 15,000 (experiments made with calibrated 'Cellophane' membranes) The first results concerning the quantitative amino-acid composition indicate that the new lysozyme is not identical with hen's egg white lysozyme

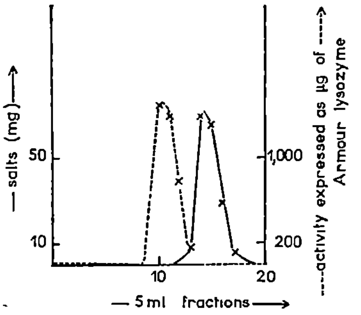

Fig 2

In any event the new lytic enzyme is a lysozyme as it possesses the principal properties of this group it is a basic protein, with a molecular weight near 15,000, stable at acid *p*H unstable at alkaline *p*H, active against suspensions of *M lysodeikticus*, and liberating by its action on an appropriate substrate compounds which can be detected by reagents for reducing sugars and for *N*-acetylhexosamines

Purification and Concentration of Dye-Protein Conjugates by Gel Filtration

It was shown by Porath and Flodin[1] that filtration through cross-linked dextran gels served as a simple method for the separation of materials of varying molecular size This procedure has now been found to be of particular value for the purification of antibody-fluorescent dye conjugates for use in the Coon's[2] technique, since unconjugated dye and dye impurities are removed so that non-specific staining of the tissues has thereby been greatly reduced or abolished

Conjugates of rhodamine[3] and fluorescein isothiocyanate[4] with (*a*) the γ-globulin fraction separated by cold ethanol[5] of rabbit antisera directed against human γ-globulin and β-lipoprotein, (*b*) with whole goat anti-rabbit antiserum and with whole rabbit anti-hen antiserum, were treated as follows Columns of 'Sephadex *G*–25' (Pharmacia, Ltd , Uppsala) were prepared by shaking 10 gm of 'Medium Sephadex *G*–25' (100–250 mesh) with 200 ml of sodium chloride phosphate buffer at *p*H 7 4 for 1 hr allowing the gel to sediment and decanting the supernatant (including any fine particles) This procedure was repeated twice The swollen gel was then suspended in a fresh volume of 200 ml of buffer and slurried into a burette, the lower end of which was plugged with glass wool Columns varying in length from 10 to 30 cm × 0 6 cm diameter were constructed, care being taken to obtain even packing of the gel The 'void volume' of the column was determined with indian ink

2–5 ml aliquots of the protein solutions labelled with dye were applied to the top of the column and allowed to filter through at room temperature When the conjugate had soaked into the gel, it was eluted with phosphate-saline buffer at *p*H 7 4 Measured volumes of the eluate were collected, the optical density measured at 280 mμ for protein, at 490 mμ (absorption maximum for fluorescein) and 560 mμ (absorption maximum for rhodamine) Aliquots from each eluate were also examined by the Ouchterlony[6] technique and its modification by Gell[7] against the appropriate antigens for identification and titration of antibody The eluted conjugate was compared with the original (untreated) material by paper electrophoresis It was also tested by application to sections cut at – 25° C of mouse- and rat-liver taken from animals injected intravenously with the appropriate antigens and killed immediately, and to human pathological material

It can be seen from the elution diagram (Fig 1) that the peak due to protein corresponds to that due to dye in the volume of eluate immediately following the void volume of the column It was repeatedly observed that a second protein peak (marked by an arrow in Fig 1) occurred, accompanied by only a slight peak in dye absorption, suggesting partial fractionation of protein which, under the conditions employed for conjugation in these experiments, was less completely labelled with fluorochrome Further elution of the column gave fractions giving the characteristic absorption of dye alone, unaccompanied by protein

This sequence could also be observed visually since, during elution, a band of coloured conjugates could be seen to separate from coloured bands of free dye. In the case of rhodamine isothiocyanate, four or five bands differing in colour were seen, suggesting the presence of several impurities in the batch utilized

It is interesting that each of the major glycolipids occurring in plants (the sulpholipid and two β-D-galactosyl diglycerides[8,9]) possesses a linkage which may be cleaved by β-galactosidase.

We are indebted to Prof. R G. Wolfe, of the University of Oregon, for the β-galactosidase preparation, and to Prof F J Reithel, of the same University, for his interest in this work

Interaction between Lysozyme and a Phospholipid of Neoplastic Tissue (Oncolipin)

LYSOZYME is a basic protein, tending to form complexes with fatty acids, aliphatic long-chain alcohols[1], alkyl sulphates[1,2], colic acids[3], and cephalins[4] Interaction promoted by lysozyme towards Rous sarcoma phosphatides is of particular interest[5]

We have examined the possibility of lysozyme producing insoluble complexes with a phospholipid (oncolipin) isolated in malignant tissues by Aoyama[6]

Tests on interaction have been performed on phosphate 0 067 buffers, using Sorensen's technique

Oncolipin was isolated from Yoshida's ascite sarcoma in rats This sarcomatous phospholipid is suspended in saline solution and the above suspension is used for preparing the 0 01 per cent solution of the substance contained in phosphate buffers, at *p*H ranging from 5 9 to 8 2

Table 1 TURBIDITY RELATED TO HYDROGEN-ION CONCENTRATION, IN SÖRENSEN'S PHOSPHATE BUFFERS

Sample (per cent)	Hydrogen-ion concentration (*p*H) 5 9	6 6	7 1	7 6	8 0	8 2
Lysozyme 0 05	0 004	0 004	0 004	0 004	0 004	0 004
Oncolipin 0 01	0 022	0 020	0 024	0 027	0 029	0 027
Oncolipin 0 01 + Lysozyme 0 001	0 036	0 034	0 032	0 038	0 041	0 038
Oncolipin 0 01 + Lysozyme 0 005	0 051	0 053	0 061	0 065	0 068	0 068

The 0 01 per cent solution of oncolipin in phosphate buffers is slightly turbid By addition of lysozyme, the turbidity becomes more evident, and proportionally to the added quantity of the enzyme

It is concluded that lysozyme interacts with oncolipin, at saline hydrogen-ion concentrations, by promoting formation of insoluble complexes This behaviour of lysozyme is like that of another basic protein, namely salmine, being also an insoluble product interacting with oncolipin, at *p*H 6 8–7 0 (ref 6)

Lysozyme from Human Milk

CONTINUING our research on lysozymes from different origins[1], we were interested in the purification of a human lysozyme Some preliminary experiments have indicated that human placenta, saliva and spleen contain lysozymes, approximately 4, 10 and 40 mgm /kgm respectively (quantities expressed in mgm of hen's egg white lysozyme). In contrast with cow's milk, we have found that human milk contains a lysozyme (40 mgm /l expressed in mgm of hen's egg white lysozyme)

We now report the isolation of this new lysozyme which we obtained in a chromatographically pure state.

The purification includes three steps

(1) Adsorption of the lysozyme on 'Amberlite *CG*–50' buffered with a 0 2 *M* phosphate buffer of *p*H 6 5 50 ml of 'Amberlite' are added to 1 litre of milk and the mixture is stirred for 4 hr The resin is then washed with water and the lysozyme is eluted with a 0 8 *M* phosphate buffer of *p*H 6 5. After dialysis against water at 2° C and lyophilization, a 'primary material' is obtained the lysozyme has undergone a 250-fold purification

(2) Chromatography of the primary material on carboxymethylcellulose The conditions are indicated in Fig 1 200 mgm of the primary material are chromatographed on a 40 × 1 8 cm column at 20° Lysozyme activity was determined by its bacteriolytic action on *Micrococcus lysodeikticus*[2] After re-chromatography of the lysozyme-containing fractions in the same conditions, a symmetrical peak, active against *M lysodeikticus*, is obtained where the specific activity is constant In this way, the primary material was again purified 7–8 times

(3) Desalting of human lysozyme on 'Sephadex *G*–50' The lysozyme-containing fractions after chromatography on carboxymethylcellulose are pooled, dialysed against water at 2° C and lyophilized

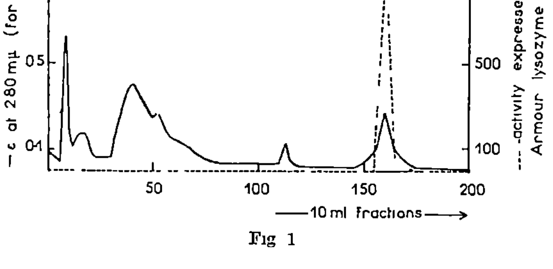

Fig 1

unpublished results) A serious criticism of all this work is that the identification of cystine, or its oxidation product cysteic acid, depends on non-specific colour reactions, and its presence is inferred rather than proved

It is now shown that to isolate the 2 4-dinitrophenyl derivative of cysteic acid from silk hydrolysates in quantities sufficient for positive identification by analysis is possible The material isolated can be determined quantitatively, for example, colorimetrically using a Spekker photoelectric absorptiometer, and the minimum cystine content of silk can thus be found Preliminary work indicates that for *Bombyx mori* this value is about 0 13 per cent The analytical aspects of this work will be discussed elsewhere, but in agreement with other workers[1,2] it seems very probable that this figure is near the true value The isolation of the cystine derivative was performed as follows

Silk fibroin (*Bombyx mori*) was degummed in solution of *p*H 1 5 at 95° C (ref 5), the usual alkaline method being avoided to prevent destruction of cystine The washed and dried fibroin (10 gm) was refluxed for 8 hr with hydrochloric acid (150 ml) and the solution evaporated to dryness *in vacuo* over solid sodium hydroxide The residue was dissolved in water (200 ml) neutralized with sodium bicarbonate (20 gm) and further sodium bicarbonate (40 gm) was added together with 2 4-dinitrofluorobenzene (25 ml) in ethanol (300 ml) The whole was shaken for 12 hr in an open flask and filtered The residue was washed with water (100 ml) and the washings, together with more water (300 ml), were added to the alcoholic solution The solution of the dinitrophenyl derivatives was extracted with ether (ethereal solution rejected), acidified with concentrated hydrochloric acid and extracted twice more with ether The ethereal solution of the dinitrophenyl derivatives was evaporated to dryness, 4 per cent performic acid (50 ml) added, the solution allowed to stand overnight and again evaporated to dryness The residue was shaken for 1 hr with water (50 ml), filtered and the solid extracted twice more with two further volumes (50 ml each) of water The combined aqueous extracts were extracted twice with ether (ethereal extracts rejected) and evaporated to 5 ml

Electrophoresis of this solution was carried out using a Shandon continuous electrophoresis apparatus (No 2520) with Whatman 3 *MM* paper using 33 per cent acetic acid as solvent It was more satisfactory to dispense with the nylon envelopes enclosing the electrodes Using 300 V which gave a current of 16 m amp the yellow solution of the dinitrophenyl derivatives separated into two sharp bands Band I moved vertically down the paper with a slight deviation towards the cathode, the solution from this band being rejected A second band (II) of equal intensity moved strongly towards the anode The solution from band II was collected and evaporated to dryness The orange-brown very deliquescent solid was dissolved in acetone, filtered and carbon tetrachloride added to the solution The whole was evaporated to dryness and kept over phosphorus pentoxide This material and the authentic dinitrophenyl derivative of cysteic acid migrated identically when subjected to electrophoresis Yield, 35 4 mgm

Found (Weiler and Strauss) C, 32 8, H, 3 0, N, 11 8, S, 9 0 $\mathrm{C_9H_9O_9N_3S}$ requires C, 32 3, H, 2 7, N, 12 5, S, 9 5 Synthetic $\mathrm{HO_3SCH_2CH(COOH)\text{-}NHC_6H_3(NO_2)_2}$ (found) C 32 0, H, 3 0, N, 11 9, S, 9 3

Hydrolysis of α-Sulphoquinovosides by β-Galactosidase

Every photosynthetic tissue so far examined has been found to contain a high concentration of a sulpholipid[1] the structure of which has been elucidated as 6-sulpho-α-D-quinovopyranosyl-(1→1′)-2′,3′-diacyl-D-glycerol[2,3] A high concentration of the deacylated form of the sulpholipid, *G*-quinSO$_3$H, occurs in *Chlorella* and *Scenedesmus*[4] This unique glycoside is cleaved to yield glycerol and 6-sulpho-D-quinovose by a highly purified preparation of β-galactosidase from *Escherichia coli ML* 308 (ref 5)

Enzymatic reactions were carried out at *p*H 7 0 25° C with tracer amounts of *G*-quinSO$_3$H labelled with sulphur-35 with or without synthetic carrier[6] The hydrolysis followed typical first-order reaction kinetics when the radioactive substrate (approximately 10^{-8} *M*) was used without carrier Hydrolysis of *G*-quinSO$_3$H by β-galactosidase was inhibited by the addition of a normal substrate, β-D-galactopyranosyl glycerol (kindly supplied by Prof H E Carter), to the reaction medium, suggesting that the reactions of the enzyme with both types of substrate take place at the same site on the enzyme

2-Hydroxyethyl or 3-hydroxypropyl sulphoquinovoside exhibited susceptibility to hydrolysis by β-galactosidase The methyl, ethyl and *n*-propyl glycosides were, however, completely resistant The β-glycopyranoside and the furanoside isomers as well as α-D-glucopyranosyl-(1→1′)-glycerol were not affected by the enzyme Sequoyitol and (+)-pinitol (kindly supplied by Dr Laurens Anderson) did not affect the hydrolysis of the β-galactoside and *G*-quinSO$_3$H, even though they are related to each other

These observations indicated that the hydrolyses of the 6-sulphoquinovosides are abnormal but highly specific β-Galactosidase has been considered strictly specific in its substrate requirement Only glycosides with the β-D-galactopyranoside structure have been considered susceptible to its hydrolytic action[7] Since the enzyme attacks certain sulphoquinovosides, as well as β-galactosides, the active site[7] should bind both types of substrate Although it is difficult to establish a mechanism at this stage, it is interesting that the distances between the oxygen atoms on carbons 1 and 4 are equal in both substrates and that the 2′- or 3′-hydroxyl group of the glycerol and one of the oxygen atoms of the sulphonic acid of *G*-quinSO$_3$H may occupy relative positions identical with those of the hydroxyl groups of carbons 2 and 3, respectively, of the β-D-galactopyranoside Since a hydroxyl group of the aglycone was essential for the susceptibility to β-galactosidase action, it must play a part in determining the specificity of the enzyme gelatin.) In an earlier communication[3] dealing mainly with inhibition of gelation of gelatin by alkaline copper (II), it was reported that a cobalt (II) complex prepared at *p*H 11.5 also prevented gelation. The correct reading is that a *p*H 11.5 nickel (II) complex, λ_{max} 435 mμ, prevented gelation, and that on acidification gelation occurred. The cobalt complex reported earlier was formed at higher alkalinity and was actually the cobalt (III) complex. At that time the cobalt (II) complex was not observed because the very slow adjustment of *p*H permitted oxidation to complex *B* without forming a noticeable amount of complex *A*.

Formation of 2-Heptanone from Caprylic Acid by Spores of Various Filamentous Fungi

IT was shown recently that washed, non-germinating spores of *Penicillium roqueforti* are capable of producing 2-heptanone from caprylic acid[1]. In examining the mechanism of this reaction[2], other fungal spores were examined for their ability to produce a ketone from the fatty acid. It is significant that spores from almost half the fungi selected converted caprylic acid to heptanone, thus indicating the more general occurrence of a reaction thought to be limited to only a few moulds.

The fungi were grown on tomato juice–agar slants in Roux bottles, and after incubation at 25° C. for 3–10 days (depending on the growth-rate of a particular fungus) the spores were collected by adding water to the bottle and scraping the surface of the mycelium with a flattened metal rod. This mixture was then filtered through several layers of cheesecloth to remove bits of agar and hyphal cells. The spores were removed from suspension by centrifugation and then 'washed' several times in distilled water by centrifugation. The spore concentration was adjusted to 10^9/ml. by using a conventional hæmacytometer. Ketone-forming activity remained constant over a period of several months when the spores were stored in water at 4° C.

To avoid using large amounts of spores, which required more time in culturing and collection, the reaction was conducted in Warburg vessels. The reaction mixture consisted of 1.0 ml. of spore suspension, 1.0 ml. of 0.5 *M* phosphate buffer at *p*H 6.0 or 7.0 and 0.2 ml. of 0.1 *M* sodium caprylate; 0.2 ml. of 20 per cent potassium hydroxide was placed in the centre well to absorb carbon dioxide. Thus, the oxygen consumption of the spores could be followed manometrically and the general direction and rate of the reaction could be observed. Heptanone production was proportional to the consumption of oxygen; if no uptake of oxygen was observed, no heptanone was produced. After 3–5 hr. the Warburg vessels were removed from the bath and the contents of the vessels were steam-distilled directly into 1.0 ml. of a 0.1 per cent solution of 2,4-dinitrophenylhydrazine. The samples, collected in the hydrazine solution, were stored at 4° C. over-night. The following day the hydrazone crystals were washed, recrystallized from hot 95 per cent ethanol and the melting points determined. The hydrazones were also chromatographed at room temperature in a closed glass cylinder with absolute methanol/water (9 : 1 by volume) as the developing solvent. The compounds were spotted on a sheet of Whatman No. 1 filter paper and after 6 hr. development the R_F of the unknown was compared with that of the known hydrazone of 2-heptanone.

It is noteworthy that spores from the majority of the *Aspergillus* sp. (9 out of 11) and *Penicillium* sp. (9 out of 12) and some related moulds including *Paecilomyces varioti* and *Scaputariopsis brevicqulis* rapidly converted caprylate to 2-heptanone. However, none of the spores of Mucorales (*Mucor hiemalis*, *Mucor mucedo*, *Phycomyces blakesleeanus*, *Rhizopus stolonifer*, *Thamnidium elegans*, and others) was capable of the reaction.

Spores of *Penicillium roqueforti* and *Aspergillus ochraceus* were found to produce identically the same amount of 2-heptanone. Some of the fungal spores produced more ketone at *p*H 6.0 and others more at *p*H 7.0. Although the reaction with some of the spores may have occurred at a lower or higher *p*H, our only interest in these particular investigations was to determine the range of the reaction among the fungi selected. The pathway for the conversion of fatty acids to ketones by spores of filamentous fungi is being investigated and the results of these experiments will be published shortly.

We are indebted to Prof. W. F. Whittingham and Prof. K. B. Raper for furnishing the cultures for these experiments. This work was supported in part by grant *E*-1201 from the U.S. National Institutes of Health.

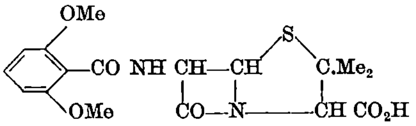
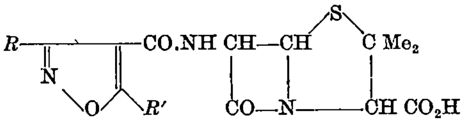
Isolation of a Cystine Derivative from Silk

CONSIDERABLE doubt exists as to whether silk fibroin (*Bombyx mori*) contains a small amount of cystine or whether this amino-acid is entirely absent. Apart from any biological significance, even a very small quantity of cystine, depending on its mode of incorporation, could have a considerable influence on the molecular weight of fibroin.

Schroeder and Kay[1], using ion-exchange chromatography, reported the presence of 0.17 per cent cystine in silk, and later Zuber, Ziegler and Zahn[2] estimated the cystine by an electrophoretic method after oxidation of the fibroin as 0.12 per cent. In recent reviews on silk[3,4], however, no reference is made to its cystine content and it has been asserted that sulphur-containing amino-acids are entirely absent and the claim that silk fibroin contains 0.12 per cent cystine cannot be reconciled with the analytical results so far available[4]. In these laboratories it has been found possible apparently to detect cystine in silk hydrolysates by both paper and ion-exchange chromatography and the Shinohara method (Earland, C., Stell, J. G. P., Lodge, R. S., and Raven, D. J., 1·3 and 35° C all have the same half-life of 160 min. as determined by a previously reported method[4] whereas the half-life of methicillin under the same conditions is between 2 and 3 minutes.



(I)



(II)

A solution of 5-methyl-3-phenylisoxazole-4-carbonyl chloride in acetone was added to a stirred solution of 6-aminopenicillanic acid and sodium bicarbonate in aqueous acetone. After 1 hr acetone was removed, the mixture was acidified, and 5-methyl-3-phenyl-4-isoxazolylpenicillin was extracted into methyl isobutyl ketone. The clarified extracts were then treated with sodium 2-ethylhexoate in isopropanol, whereupon the hydrated sodium salt of the penicillin crystallized in high yield, m.p. 188° (decomp.), $[\alpha]_D^{20}$ + 201° (*c* = 1 in water) (Found: C, 52·0; H, 4·9; N, 9·0; S, 7·1; Na, 5·2. $C_{19}H_{18}N_3O_5SNa, H_2O$ requires: C, 51·7; H, 4·5; N, 9·5; S, 7·3; Na, 5·2 per cent). A similar reaction with 3-methyl-5-phenyl-isoxazole-4-carbonyl chloride gave the anhydrous sodium salt of 3-methyl-5-phenyl-4-isoxazolylpenicillin, m.p. 239° (decomp.), $[\alpha]_D^{20}$ + 226° (*c* = 1 in water) (Found: C, 53·7; H, 4·7; N, 9·8; S, 7·6; Na, 5·0. $C_{19}H_{18}N_3O_5SNa$ requires: C, 53·9; H, 4·3; N, 9·9; S, 7·6; Na, 5·4 per cent.)

Details of the preparation of many analogous 3,5-disubstituted 4-isoxazolylpenicillins will be reported elsewhere. Several of the products are at present undergoing clinical evaluation.

Cobalt Complexes of Proteins and Polypeptides

WE wish to present evidence for the formation of two types of cobalt complexes of proteins and polypeptides in which cobalt is probably bound to the peptide groups. A variety of proteins (for example, gelatin, pepsin, edestin, lysozyme, chymotrypsinogen), as well as tetraglycine and poly-DL-alanine, give the complexes, but most of the work has been carried out with commercial gelatin.

Complex *A* is obtained at high alkalinity as a clear violet solution, λ_{max} 560 mμ. On acidification of the violet complex immediately after formation, the pink colour of cobalt (II) ion is restored. A typical preparation is made as follows. To a mixture of 10 ml. of 10 per cent aqueous gelatin, 1 ml. of 0·35 *M* cobalt (II) sulphate and 4 ml. water, there is added quickly 5 ml. of 4 *M* potassium hydroxide (final hydroxide concentration 1 *M*). The optical density is about 0·3 (0·1-cm cell) at 560 mμ. Complexes have also been prepared starting with 2 per cent gelatin solutions, the final alkali concentration also being 1 *M*. The more dilute gelatin was used when spectra of complexes of higher cobalt to peptide ratios were measured. The highest molar ratio of cobalt to peptide groups that was found to give the clear violet solution was about 1 : 10. At slightly higher ratios the solutions showed a Tyndall effect probably caused by colloidal cobaltous hydroxide, but were transparent by transmitted light. At still higher cobalt to peptide ratios, the rose-coloured form of cobalt (II) hydroxide was precipitated.

The lowest hydroxide concentration at which a fluid complex of gelatin can be formed is about 0·3 *M*. Below 0·3 *M* alkali a jelly of gelatin combined with the blue form of cobalt (II) hydroxide is produced.

The red-brown complex *B* is formed on ageing of complex *A* in air, the transformation beginning in a few minutes in the case of gelatin, in a few seconds with some other proteins. In an open test-tube the change to red-brown is observed to proceed slowly from the top downwards. A similar change is produced immediately by addition of hydrogen peroxide or hypobromite ion. When a gelatin–cobalt solution was mixed with alkali in vacuum, the violet colour persisted for 22 hr (although some brown precipitate formed toward the end), at which time air was admitted, resulting in conversion to complex *B* in a few minutes. The absorption maximum of complex *B* is 460–470 mμ. Acidification of complex *B* does not restore the cobalt (II) colour, but gives a light brown solution of λ_{max} 480 mμ.

Apparently *A* is a cobalt (II) complex, while *B* is a cobalt (III) complex. Ligation of cobalt to the peptide groups, with ionization of the peptide hydrogen, is suggested by the high alkalinity required and by the lack of reactivity of poly-L-proline, poly-L-hydroxyproline or poly-sarcosine. The complexes of gelatin with high cobalt contents do not gel at 0°, while a control lacking cobalt, but at the same alkali concentration, does gel. The solutions gel after acidification. By analogy with the biuret-type copper and nickel complexes, which are known to be peptide complexes[1] and also do not gel, we may regard the cobalt complexes as peptide complexes. Tetraglycine binds one cobalt to two tetraglycines, assuming the cobalt to be octahedral it is possible that the ligating groups are the six peptide groups and not the terminal groups. Complex *B* is probably related to the wine-red complexes of cobalt (III) with glycylglycine and glycylglycylglycine which Manyak, Murphy and Martell proposed as having cobalt–peptide (as well as cobalt–amino and cobalt–carboxyl) bonds[2]. The spectra of complexes *A* and *B* prepared from gelatins in which all the amino-groups had been acetylated or 70 per cent of the guanidino groups removed by alkaline hypobromite were the same as those of the complexes of the parent gelatin. (To prevent oxidation of complex *A* a few μgm. of bisulphite were required to destroy traces of positive bromine not removed by dialysis of the hypobromite-treated

Consistently low calcium values were obtained by the method of direct dilution with water as might be expected due to the presence of interfering phosphorus and protein. The other three methods of preparing solutions for measurement by the atomic absorption technique gave results which were in close agreement and which were in good correlation with calcium values obtained by oxalate–permanganate titration.

Experiments on the recovery of calcium added to saliva in known amounts indicated that, with the exception of direct dilution with water, atomic absorption analysis gave acceptable results. Saliva samples diluted with ethylenediamine tetraacetate acid gave an average recovery of 98.6 per cent and deproteinized saliva containing strontium suppressor gave an average recovery of 99.0 per cent.

From the results in Table 1 it may be deduced that the secretion of the submaxillary salivary glands (6.8 mgm. per cent calcium) contains about 50 per cent more calcium than that of the parotid gland (4.1 mgm. per cent calcium) under conditions of exogenous stimulation. The higher frequency of calculus surrounding lower anterior teeth and their relative immunity to dental caries may be attributable to their proximity to the orifices of the ducts of the submaxillary glands and the higher calcium content of this secretion.

Using Schneyer's data[5] for the proportion of individual gland pair secretions of total stimulated saliva (submaxillary 63 per cent, parotid 34 per cent) and neglecting the contribution of sublingual and other minor glands, the calcium content of whole saliva was calculated as 5.9 mgm. per cent

$$\left(\frac{6.1 \times 63 + 4.1 \times 34}{97}\right)$$

Values for calcium content of whole saliva shown in Tables 1 and 2 are in good agreement with this theoretical amount.

The 'debris' and particulate matter which is inevitably present in whole saliva interferes with some of the volumetric and colorimetric methods for determining salivary calcium content. Many investigators have therefore carried out preliminary centrifugation of the whole saliva. Provided that there is no clogging of the capillary tube of the atomizer, the atomic absorption spectrophotometric method can be applied directly to whole saliva diluted in ethylenediamine tetraacetic acid without prior centrifugation. Table 2 shows the results of duplicate calcium analyses on five samples of whole saliva both before treatment and on the supernatant and precipitate following centrifugation. My results indicate an approximately 22 per cent lower calcium value for centrifuged saliva.

Table 2. CALCIUM CONTENT OF WHOLE SALIVA* (MGM./100 ML.) ESTIMATED BY DIRECT DILUTION WITH ETHYLENEDIAMINE TETRAACETIC ACID

	5.42	4.40	1.15

* Stimulated by paraffin.

† Centrifuged at 4,000–4,500 r.p.m. for 10 min.

With stimulation by citric acid, very little variation was found in the calcium content of parotid and submaxillary saliva collected as consecutive aliquots during 1.5-min. intervals for 15 min. Over the period studied the glands showed no evidence of depletion of the calcium content of the secretion. There appeared to be no appreciable difference in the calcium content of right and left parotid gland saliva collected simultaneously or in the flow-rate.

I am indebted to Dr. J. B. Willis for his suggestions and Dr. K. W. Knox for his interest and encouragement in these experiments. I also wish to thank Mr. B. Gow for his invaluable assistance in assembling the atomic absorption equipment. This work was supported by the National Health and Medical Research Council of Australia.

New Penicillins Stable towards Both Acid and Penicillinase

FOLLOWING on the isolation in these Laboratories of 6-aminopenicillanic acid[1], we have used it to synthesize many novel penicillins, with particular emphasis on structures which resist inactivation by staphylococcal penicillinase. One class of penicillins possessing this valuable property has been obtained by acylating 6-aminopenicillanic acid with aromatic or heteroaromatic carboxylic acid chlorides substituted in both *ortho* positions. When the ring structure of the side-chain acid is six-membered, almost any pair of *ortho* substituents confer marked stability towards penicillinase, but when it is five-membered one or both of the substituents must be relatively bulky, for example, phenyl or substituted phenyl. Such findings illustrate the primary importance of steric effects in determining stability towards penicillinase. In this respect the chemical constitution of the side-chain is of much less significance, although it has a profound influence on antibacterial activity and on stability towards acids.

The first such penicillin to be synthesized[2], 2,6-dimethoxyphenylpenicillin (I, methicillin), has proved very effective in staphylococcal infections although, since it is unstable to acid and is poorly absorbed when given by mouth, it has to be administered by injection. We have now prepared a series of 3,5-disubstituted 4-isoxazolylpenicillins[3] (II) many of which, especially those in which one of the *ortho* substituents is a phenyl or substituted phenyl group and the other is a methyl or other lower alkyl group, exhibit high antibacterial activity both *in vitro* and *in vivo*. (We thank Dr. G. N. Rolinson, Mr. D. M. Brown, and their colleagues for carrying out these tests.) Furthermore, they are relatively stable at low pH and suitable for oral administration. Thus, 5-methyl-3-phenyl-4-isoxazolylpenicillin (II, $R = \text{Ph}$, $R' = \text{Me}$), 3-methyl-5-phenyl-4-isoxazolylpenicillin (II, $R = \text{Me}$, $R' = \text{Ph}$), and phenoxymethylpenicillin (penicillin V) in 50 per cent aqueous ethanol at pH

Rotational Analysis of the $A^2\Pi$–$X^2\Sigma^+$ System of MgCl

ALTHOUGH the internuclear distances in the diatomic halides of the typical elements of Groups I and III are known, often very precisely, few values are available for the diatomic alkaline earth halides. Following the rotational analysis[1] of the $C^2\Pi$–$X^2\Sigma^+$ system of CaCl, we have now completed an analysis of the 0–0 and part of the 0–1 bands of the $A^2\Pi$–$X^2\Sigma^+$ system of MgCl, from absorption spectrograms taken in a third order of a 6.5-m. grating instrument.

The analysis of the longer-wave-length sub-bands of the 0–0 and 0–1 bands was straightforward, but lines of the shorter wave-length sub-bands are badly blended and overlapped, and the 1–0 bands are too poorly resolved for analysis. However, a satisfactory check was provided by the analysis of the longer wave-length component of the 0–0 band of ^{37}MgCl. The bands observed present no unusual features. As in CaCl, the spin-splitting in the ground-state was too small to be detected, so that the satellite branches were everywhere blended with the main branches. Λ-type doubling in the $^2\Pi$ state is also very small, and the lines in the shorter wave-length sub-bands, presumed to involve $^2\Pi_{\frac{1}{2}}$, are too overlapped to show whether this state is, in fact, inverted, as expected from the likely electron configuration.

Table 1. SUMMARY OF CONSTANTS (^{35}MgCl)

State	T_0	ΔG_{01}	B_0	$10^3\ \alpha$	$10^7\ D$	r_e, Å
$A^2\Pi_{1/2}$	26,535.89		0.25116	(1.8)	2.2_5	2.171_6
$A^2\Pi_{3/2}$	26,481.95		0.24914	(1.8)	2.2_5	2.176_4
$X^2\Sigma^+$	0	462.12	0.24423	1.5_8	2.5_2	2.198_6

A summary of the constants obtained in the present work is given in Table 1. The value for the internuclear distance in the ground-state is r_e = 2.199 Å, not significantly different from the value 2.18 ± 0.02 Å obtained for the gaseous dihalide, $MgCl_2$, by electron diffraction[2].

BIOCHEMISTRY

Application of Atomic Absorption Spectroscopy to the Determination of Calcium in Saliva

THE importance of salivary calcium concentration of the environment in the solubility of tooth and enamel is readily apparent. As with other biological fluids, numerous methods, ranging from classical oxalate-permanganate titration and emission flame photometry to the more recent complexometric and colorimetric techniques, have been used to estimate the calcium content of saliva. Unfortunately most of these methods have certain disadvantages. The oxalate-permanganate method requires relatively large amounts of saliva, time-consuming centrifugation, washing and titration within a narrow temperature-range. Its accuracy has been questioned because of incomplete precipitation of the oxalate or loss of some calcium oxalate during the washing process[1]. Another devious procedure involves a complexometric analysis of calcium and magnesium in saliva followed by a separate colorimetric determination of magnesium, calcium being obtained as the difference[2]. Several complexon-titration techniques using eriochrome black *T*, murexide or plasmo corinth indicators were tested on saliva. They were found unsatisfactory because the colour shift at the end-point was either too gradual and indistinct or, in the case of murexide, the colour faded too rapidly.

Saliva stimulated by application of citric acid to tongue.
‡ Sample centrifuged to remove particulate matter.

Willis's method[3] for the determination of calcium in blood serum by atomic absorption spectroscopy has been adapted for salivary calcium analysis and found to be accurate and rapid, requiring as little as 0.1 ml. of saliva. The apparatus used in these experiments has been previously described[4]. A Hilger *D* 290 monochromator was found satisfactory in this system.

Certain normal constituents of saliva can interfere in the determination of calcium by the atomic absorption method. Sodium enhances calcium absorption, phosphorus depresses the calcium absorption and the interference of protein appears to be variable, depending on the type of flame used[3]. Saliva can be deproteinized by the standard procedure of adding trichloracetic acid and centrifugation. Large concentrations of [Sr^{++}] or [La^{+++}] can compete with calcium for combination with phosphorus and suppress this interference. Ethylenediamine tetraacetic acid, by complexing calcium, can also overcome phosphorus interference and presumably compete with proteins for calcium.

The results of calcium estimations on saliva are shown in Table 1. The saliva was diluted 1 : 10 by one of the following methods: (*a*) direct dilution with water, (*b*) dilution with water and solution of the disodium salt of ethylenediamine tetraacetic acid, final concentration 10,000 p.p.m. ethylenediamine tetraacetic acid, (*c*) dilution with water, strontium chloride solution and trichloracetic acid: final concentration 2,500 p.p.m. strontium and 4 per cent trichloracetic acid. The sample was centrifuged and measurements made on the supernatant, (*d*) similar to method (*c*) but lanthanum chloride was used as a phosphate 'suppressor', final concentration 10,000 p.p.m. lanthanum.

The saliva thus prepared was measured relative to standard calcium solutions containing respectively (*a*) 60 p.p.m. sodium (approximate level in 1 : 10 diluted saliva), (*b*) 10,000 p.p.m. ethylenediamine tetraacetic acid, (*c*) 5,500 p.p.m. strontium, 60 p.p.m. sodium and 4 per cent trichloracetic acid, (*d*) 10,000 p.p.m. lanthanum, 60 p.p.m. sodium and 4 per cent trichloracetic acid.

Sedimentation of β-Lactoglobulin (*A,B*) under Dissociating Conditions in Acid Solution

Evidence that β-lactoglobulin molecules dissociate into halves in the *p*H region 1 6–4 has been presented by Timasheff, Townend and Weinberger[1-3], and they have shown[3] that there is reasonable agreement between the results obtained by the complementary methods of ultracentrifugation and light-scattering The overall picture which emerges is of a dumb-bell-shaped[4] lactoglobulin molecule, of axial ratio 2, dissociating reversibly at 25° below *p*H 4 into two spherical sub-units of equal size According to light-scattering data, and on the assumption of a molecule of weight 36,000, the dissociation constant at *p*H 1 6 is 2 5 × 10^{-4} mol /l. and at *p*H 3 5 is 4 3 × 10^{-6} mol /l [3]

We have now attempted to carry a comparison of the two methods a stage further, and to calculate the implications for sedimentation of accepting these values from light-scattering of the dissociation constants

The main effect of dissociation on sedimentation is seen in a departure of the sedimentation velocity–concentration curve from the normal form Weak dissociation leads to a high maximum, whereas strong dissociation leads to a lower maximum, or if sufficiently strong, to no maximum and only a change of slope[5] In Fig 1 theoretical curves are shown for sedimentation at *p*H 1 6 and 3 5 The sedimentation velocity–concentration curves marked *a* and *b* have been constructed on the basis of the light-scattering dissociation constants, together with the following minimal assumptions (1) The limiting sedimentation coefficient of the sub-unit (monomer) is 1 89 svedbergs. (2) The whole molecule (dimer) moves relatively faster than the sub-unit by the factor $2^{2/3}$ because of its weight, and 1/1 044 because of its shape[6], that is, $s_2 = 1\ 52\ s_1$ (3) The sedimentation coefficient for each species considered alone obeys the relation $s = s_0\ (1/1 + gc)$, where g is a constant (4) At *p*H 1 6, the maximum value of the sedimentation coefficient, measured using the boundary median, is 2 34 svedbergs This fixes the value of g as 0 1 (gm /100 ml $)^{-1}$

Whether the curves are based on a weight average[7], or the position of the median of the boundary[5,8], is not very material for this simple monomer–dimer system, as was shown earlier[5]

The experimental points in Fig 1 are taken from the work of Townend, Weinberger and Timasheff[3], and include one check point not hitherto published (Timasheff and Townend, personal communication) It is seen that they lie fairly near the theoretical curves *a* and *b* when considered as a whole, but that there is an obvious discrepancy at low concentrations at *p*H 3 5 It is difficult to see how a dissociation constant as great as 4 3 × 10^{-6} mol /l can be reconciled with the sedimentation results at the two lower concentrations there The effect on the position of the theoretical curve of reducing the value of the dissociation constant ten-fold is shown in Fig 1 (curve *c*) It will be interesting to see whether future work on purified *A* and *B* lactoglobulin eliminates this conflict between the interpretation of light-scattering and ultracentrifuge data.

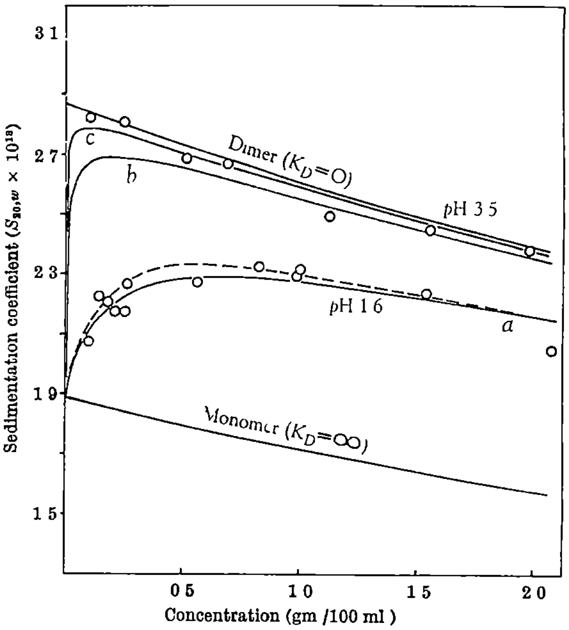

Fig 1. Sedimentation of lactoglobulin (*A,B*) under dissociating conditions *a*, K_D = 2 5 × 10^{-4} mol /l , *b* K_D = 4 3 × 10^{-6} mol /l , *c*, K_D = 4 3 × 10^{-7} mol /l ——, Weight average (theory), ---, median of boundary (theory), ○, experiment (Townend, Weinberger and Timasheff, ref 3)

The value of g is in itself of some interest, since it is about twice that to be expected for a non-reacting protein near its isoelectric point This may be a reflexion of the fact that the lactoglobulin molecules are sedimenting in a highly charged condition, and that electrostatic repulsion is reducing the number of near neighbours, and hence their contribution to the net velocity of sedimentation[9]

Puzzolanic Activity and Semiconductivity of Fired Kaolin and Kaolinitic Clay

It is known that the reaction of a puzzolan with lime in the presence of water is a chemisorption process[1], and that the puzzolanic activity of a material is enhanced when its crystal structure breaks down, that is, when the material is in a highly disordered state. The enhancement of puzzolanic activity is attributed to the increased reactivity of the materials in the disordered state[2] or its lattice being in strained condition. Similarly, the observed high puzzolanic activity of volcanic ash, a natural puzzolan in the glassy phase, is considered to be the result of the highly strained condition of its lattice[3].

On the other hand, a chemisorption process depends on the electrical characteristics of the reactants[4] and the breakdown of structure of a crystal, say, through the action of heat, may produce crystals which may be semiconductors. Clay minerals, for example, on firing are changed into an intimate mixture of oxides, some of which are semiconductors. It is also possible that the defects produced in the crystal when heated under appropriate conditions may induce semiconducting properties[5]. It is therefore suggested that the effect of disorders or defects present in a natural puzzolan or introduced into a material to improve its puzzolanic activity by heating (as in burnt clays) is to render the material a semiconductor, then the reactivity with lime of a puzzolan may be a semiconductor surface reaction.

Results of work on the puzzolanic activity of kaolin (unfired, fired and fired with zinc oxide) and of a fired kaolinitic clay (fired with or without admixture of zinc oxide) have been published recently[6,7]. Electrical resistivities of some of these materials, kaolin (unfired, fired at 800° C. and fired with 0.01 per cent zinc oxide) and a kaolinitic clay (fired alone and with 0.01 per cent zinc oxide added to it), have been measured to see if these materials were semiconductors. Results are given in Fig. 1, which shows that (*a*) these materials are semiconductors (kaolin undergoes crystallographic changes during firing, hence for kaolin the values represent the resistivities of the products formed during heating) and (*b*) resistivities of these materials increase slightly when heated with zinc oxide.

If the puzzolanic activity of a material depends on its semiconducting properties, then its puzzolanic activity should alter with its electrical resistivity. When kaolin and kaolinitic clay are fired with zinc oxide there is an increase in electrical resistivity (Fig. 1). There is also an increase in puzzolanic activity (in terms of compressive strength and adsorption of lime) of these materials when fired with zinc oxide[6,7]. Similarly, there is an increase in resistivity of kaolin on firing (Fig. 1) and there is also a corresponding increase in both compressive strength and adsorption of lime of kaolin upon firing[6].

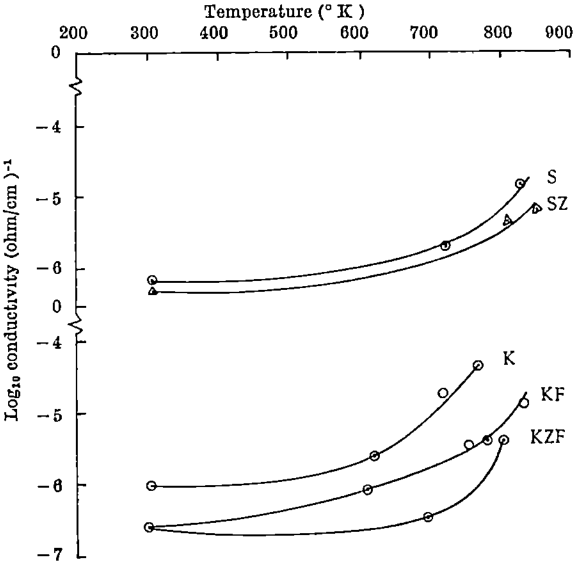

Fig. 1. Variation of electrical conductivity with temperature. K, Kaolin; KF, kaolin fired at 800° C.; KZF, kaolin + 0.01 per cent zinc oxide fired at 800° C.; S, clay fired at 800° C.; SZ, clay fired with 0.01 per cent zinc oxide at 800° C.

If adsorption of lime by a puzzolan in the presence of water is a chemisorption process on the surface of a semiconductor, there should be a change in the resistivity of the puzzolan after it has adsorbed lime in presence of water. Accordingly, resistance measurements of kaolin and kaolin fired at 800° C. were carried out at room temperature. These materials were then allowed to adsorb lime in the presence of water and their resistances (after having been thoroughly washed and dried) were again measured under similar conditions. It was found that there was a difference in the resistivities of these materials before and after they had adsorbed lime[8]. These resistance measurements were, however, not very reliable.

A natural puzzolan with a glassy structure can be a semiconductor. It is the short-range order (bonding predominantly covalent) which determines semiconductivity rather than the long-range order (structure). The general conditions to be fulfilled by a material in order that it may be a semiconductor have been given by Mooser and Pearson[9]. It will be seen that it is quite possible that many natural puzzolans satisfy these conditions.

If reactivity with lime of a puzzolan is a semiconductor surface reaction, the formation of a compound on the surface of a puzzolan will involve electron transfer and will be guided by the chemical potentials in the adsorbate and in the puzzolan[4] (that is, Fermi-level). Obviously only those semiconducting materials which have suitable Fermi-levels can behave as puzzolans.

It is therefore suggested that (i) for a material to have puzzolanic properties it must be a semiconductor; glassy-phase puzzolans are probably glassy-phase semiconductors, and (ii) reactivity with lime of a puzzolan then may be considered to be a semiconductor surface reaction.

I thank Shri A. K. Dutta, research officer of the Indian Association for the Cultivation of Science, much higher pressures and lower temperatures used in this work Indeed, recent work by Rudolph and Melton[15] and by Field[16] has shown that higher molecular weight ions become more important in the mass spectra of acetylene and of ethylene, respectively, when high pressures (up to 350μ in ethylene) are used

CHEMISTRY

Valence State of Platinum–Alumina Catalysts

Platinum-on-alumina reforming catalysts are widely used in the petroleum industry Recent work in this laboratory has shown that catalysts containing soluble platinum more readily convert paraffins to aromatics[1] Soluble platinum is that which will dissolve in either dilute hydrofluoric acid or acetylacetone. It is believed to exist as a compound involving the alumina support and the chloride present in the catalyst, and is in the plus-four valence state after solution in dilute hydrofluoric acid

To establish the valence state of soluble platinum in the catalyst, ultra-violet spectrophotometric measurements have been made on catalysts specially prepared on alumina aerogels[2] In addition, the reflectance of finely ground samples of previously pelleted platinum-on-alumina catalysts has been measured

Before spectral analyses of the transparent aerogels could be made, the platinum–chloro-alumina complex was converted to the platinum–iodo-alumina complex The exchange is necessary because the platinum–chloro-alumina complex absorbs in a region of the ultra-violet spectrum (260 mμ) where scattering by the alumina aerogel is too high to allow observation of the peak Absorption of the platinum-iodo-alumina complex in the near ultra-violet (360 mμ), however, is free of light-scattering The platinum-iodo-alumina complex was made from an all-soluble platinum–chloro-alumina aerogel catalyst by carefully treating an evacuated aerogel with a solution of potassium iodide in absolute methanol and normal pentane The exchange of chloride for iodide is straightforward, with no oxidation of platinum in the potassium iodide solution[3] The absorption spectra for aqueous iodoplatinic acid and the platinum–iodo-alumina aerogel are shown in Fig 1. Measurements were made with a Cary model 11-*MS* spectrophotometer A slight shift of the platinum–iodo-alumina peak to a longer wave-length for the aerogel, as compared with aqueous H_2PtI_6, might be due to additional complexing with the alumina Because divalent platinous iodide does not absorb in this region[3], these spectra indicate platinum, as complex on the catalyst, is present in the plus-four valence state Iodide exchange of a platinum–chloro-alumina aerogel that was insoluble in hydrofluoric acid showed no ultra-violet absorption, as indicated by the dashed line

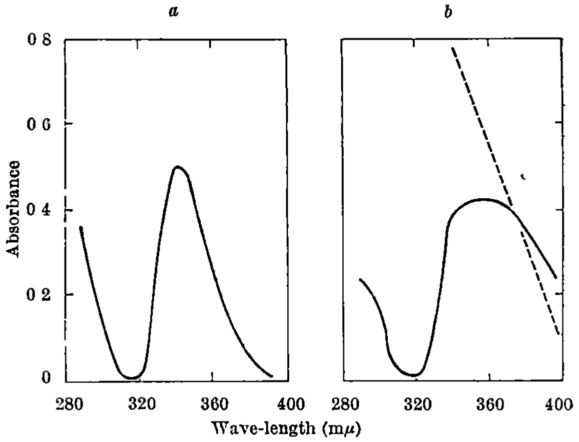

Fig 1 Ultra-violet spectra *a*, Aqueous $PtI_6^{=}$, *b*, catalyst treated with potassium iodide

Reflectance spectra of platinum catalysts are shown in Fig 2 The results were obtained with a Beckman model *DU* reflectance attachment on samples ground finer than 100 mesh Magnesium carbonate was the reference standard An absorption spectrum of aqueous chloroplatinic acid is included for reference The soluble platinum catalyst shows a small peak slightly shifted from the peak for aqueous $PtCl_6^{=}$. A sample of alumina alone and the platinum catalyst insoluble in hydrofluoric acid show no peaks

Platinum in the soluble form is thus in the octahedral plus-four valence state in the catalyst The

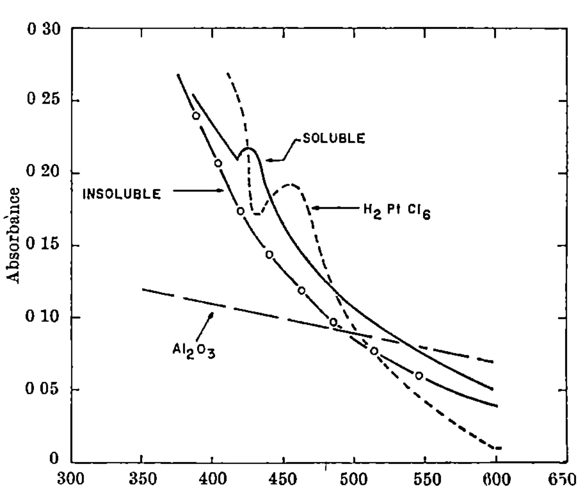

Fig 2 Reflectance spectra

warmer part was sublimed on to the cooler part. Such crystals were small in size (less than 1μ) and showed atypical shapes (Fig. 4).

As for the sublimation of the frozen droplets made up of tap water as material, it was once observed, when the sublimation occurred from inside the margin of the droplet, that the sublimed area expanded in all directions taking constantly a hexagonal shape (Fig. 5).

RADIATION CHEMISTRY

Production of High Molecular Weight Products from the Irradiation of Methane with 4-MeV. Electrons

THE effects of ionizing radiations on gaseous methane have been examined previously and the yields of hydrogen and of higher hydrocarbons up to pentane determined to within what appear to be small limits of error[1,2]. Hydrogen is the major product, while the amounts of gaseous hydrocarbons are much less and decrease rapidly with increase in molecular weight. However, there is a 10–30 per cent excess of elemental hydrogen in the products[1-3]. In fact, a large excess of hydrogen seems to be a common feature of the radiation chemistry of gaseous hydrocarbons, though not of liquids[4-6]. It has been known for some time that massive radiation doses lead to the production of liquid products from low-molecular-weight saturated hydrocarbons[7-9], while more recently a more detailed study of liquid product formation from methane and other gaseous hydrocarbons has been reported[10,11]. The nature of the liquid products and their significance in the overall radiolytic process have not been examined.

We have irradiated purified (99·98 per cent) gaseous methane in 'Pyrex' vessels with electrons from a linear accelerator. The dose-rate was about 10^{18} eV. cm.$^{-3}$ min.$^{-1}$ in methane at 1 atm., 15° C. The dosimetry was based on the yield of ethane, $G = 2{\cdot}00$, from methane after short irradiations ($<$ 1 per cent decomposition). Gaseous products were analysed by gas chromatography, liquid products by gas chromatography and mass spectrometry. The liquid was collected by centrifugation. Irradiations giving up to 30 per cent methane decomposition were carried out.

The production of gaseous products was very similar to that found by Lampe[1] except that we were unable to detect unsaturated products irrespective of the dose given. No hydrocarbons above pentanes could be detected in the gas.

Of the liquid product collected, only a small fraction (about 10 per cent) was detectable by gas chromatography at 180° C., and consisted of C_6–C_{12} hydrocarbons, the proportion of C_6 and C_7 being less than that of C_8 and C_9. A further analysis on a much less sensitive temperature programmed gas chromatography apparatus showed that the major portion of the liquid consisted of C_{14} to C_{20} hydrocarbons. A mass spectrometric analysis gave the same overall picture and also showed not only the presence of hydrocarbons with up to 27 carbon atoms per molecule, but also the absence of significant amounts of unsaturated material. Furthermore, even higher hydrocarbons were undoubtedly produced which were not collected by centrifuging the reaction vessel. Irradiation of a methane–argon mixture containing 0·65 electron fraction argon gave essentially the same yield of liquid products as with pure methane. In this case the yield was based on the total energy absorbed in the mixture, using electron fractions to convert from pure methane to the methane–argon mixture. Examination of the gas chromatograms showed, however, that the C_6–C_{12} fraction of the product from the methane–argon mixture was only about half that of the corresponding fraction obtained from pure methane. This shift to higher molecular weight products in argon–methane mixtures may have been due to a gross energy transfer from the argon to methane, resulting in a larger energy deposition per gram of methane in the mixture than in the pure methane. However, irradiation of pure methane to twice the dose given to 50–50 argon–methane mixtures still showed a much larger fraction of low molecular weight liquid products from the pure methane.

The conclusion is drawn that a process occurs both in pure methane and in methane–argon mixtures which results in the formation of high molecular weight products, and that this process is enhanced in the presence of argon (but not of xenon, as shown by other experiments).

Other work on the same systems in this Laboratory has shown some similarity in the behaviour of methane and methane–argon mixtures when irradiated to low doses. For example, the yields of ethane and propane are practically unchanged at argon electron fractions 0–0·9. However, the hydrogen yield, based as usual on the total energy given to the mixtures, is actually greater in the mixtures than in pure methane. It is noteworthy that the additional hydrogen is not scavengable. Also, the *n*-butane/isobutane ratio is significantly increased. In xenon and helium, however, the behaviour is quite different, for example, the *n*-butane/isobutane ratio in methane–xenon mixtures is only about one-third of that observed in mixtures with argon.

The results outlined briefly here indicate that a process occurs in irradiated methane which is enhanced in mixtures with argon, this process giving rise to both increased yields of high molecular weight products and of molecular hydrogen. Since only about half the hydrogen from pure methane is scavengable and the non-scavengable fraction is increased in argon mixtures, it appears likely that a non-radical process is responsible.

It is suggested that the high molecular weight products and non-scavengable hydrogen are produced by ion-molecule reactions[12,13] of the type:

$$CH_3^+ + CH_4 \rightarrow C_2H_5^+ + H_2$$
$$C_2H_5^+ + CH_4 \rightarrow C_3H_7^+ + H_2, \text{ etc.}$$

Melton[14] has recently shown mass spectrometrically that there is a large increase in the CH_3^+/CH_4^+ ratio on addition of argon to methane. The fact that $C_3H_7^+$, or any other higher ion, has not been detected in mass spectrometric studies of methane is not good evidence that this ion is absent or unimportant at the recording of that derivative for the 129-keV. line of iridium 191; the source was about 60 μc., the absorber was a strip of iridium foil 5 mm. wide and 0·05 mm. thick, and the recording took about 1 hr. The entire assembly can fit into the working gap of an electromagnet.

It is hoped to publish a more detailed description of the method, with applications, elsewhere.

Investigation with the Electron Microscope of the Sublimation of Ice Crystals at Low Temperatures

INVESTIGATIONS of ice crystals by means of the electron microscope have been made by several investigators[1-4], but most of them were based on replication techniques. Recently, Fernández-Morán[5] reported the results obtained by low-temperature microscopy; he succeeded in stabilizing ice crystals deposited on a cold substrate by maintaining them at low temperatures during observation in the electron microscope with a microbeam of very low intensity. It was noted by him that the ice crystals were predominantly cubic and hexagonal in shape at −120° C. and at −100° to 90° C., respectively, and actually showed corresponding sharp-ring diffraction patterns.

I have been investigating the freeze-drying process of micro-organisms by the use of an electron microscope in which a specimen-cooling device and a 16-mm. cinematograph were incorporated[6]. When the freeze-drying process of yeast cells was being investigated, I happened to observe the process of sublimation of ice crystals which were deposited on the film mounted on a specimen grid.

The electron microscope used for this experiment was a model 6*A*-type made by the Japan Electron Co. Yeast cell suspension as an experimental material was sprayed on a carbon–collodion film which had been designed to keep the specimen from contamination during irradiation with the electron beam. The droplets sprayed on the film were rapidly frozen to −196° C. by immersing them into liquid nitrogen. The specimen cartridge was quickly transferred into the specimen chamber of the electron microscope and settled in the specimen holder which was pre-cooled to −140° − −160° C. by contact with a cooling device refrigerated by liquid nitrogen. Electron beam intensity was controlled to be as low as possible so that the beam might not make artefacts. The electron current density used in this experiment was $5 \cdot 6 \times 10^{-4}$ amp./cm.^{2} which was sufficient for taking a cinematograph at a moving speed of 1·5 frames/sec.

Throughout the specimen field, large circular particles with diameters of 20–50μ were scattered. These proved to be droplets of yeast cell suspensions when observed in a subsequent drying process. In the interspaces numerous small particles could be seen. These particles were of cubic, hexagonal, round or other atypical shape with sizes varying from 1 to 5μ; it was quite probable that they were the ice crystals made up of water vapour condensed on the collodion film during transfer from liquid nitrogen to the specimen chamber. Electron diffraction patterns were also obtained corresponding to several crystal types.

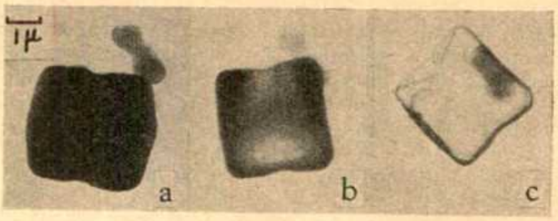

Fig. 1

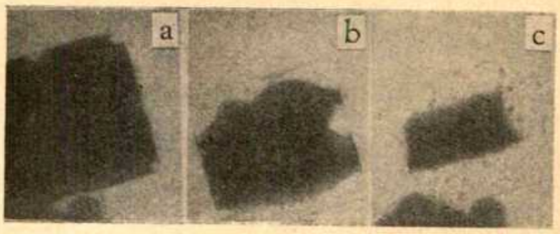

Fig. 2

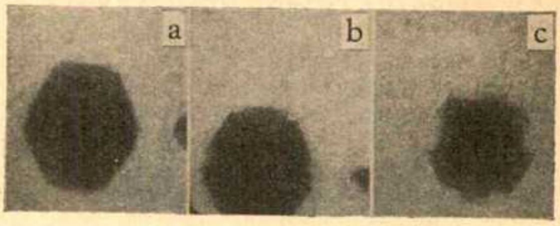

Fig. 3

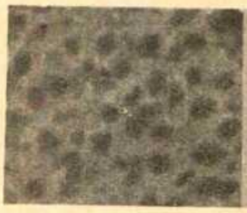

Fig. 4

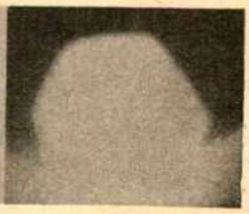

Fig. 5

After the refrigerant reservoir was raised from the specimen holder, the temperature of the specimen increased gradually. When it reached −90° or −80° C., not exactly measured, the ice crystals began to sublime. As sublimation proceeded, crystals decreased in size and sometimes suddenly disappeared from the field, being probably removed from the collodion film to the vacuum pump. In some cases, ice crystals maintained their contour even after sublimation. This fact was considered to be a kind of replication caused by the electron beam in the microscope during sublimation (Fig. 1,*a*, *b*, *c*). In rare cases it happened that the crystals of cubic and hexagonal types sublimed in such a manner that several 'worm-eaten' spots appeared at the corners of their margins (Figs. 2*a*, *b*, *c* and 3*a*, *b*, *c*). In one case where it was supposed that a temperature gradient may have arisen within the specimen, the water vapour which sublimed from ice crystals at the

$\lambda_e = 0{\cdot}584 \times 10^{-10}$ yr.$^{-1}$

δV_r = Percentage standard deviation in volume of radiogenic argon due to uncertainty in isotope ratios of argon sample.

δt = Error in age in millions of years that would be caused by a 1 per cent error in either proportion of potassium oxide or volume of radiogenic argon.

Grid references to localities refer to the National Grid.

Biotite separated from the biotite gneiss of the Eddystone Rock (obtained through the courtesy of Dr. P. A. Sabine, Geological Survey) gave a Caledonian age (375 million years) by the total volume method. This rock has in the past been generally correlated with the metamorphics of the Lizard[4]. From the experience in the Lizard it cannot be assumed that this Caledonian age is the age of crystallization of the gneiss, but it can be said that the Eddystone Gneiss forms part of the metamorphic terrain affected by the Caledonian orogenic events.

PHYSICS

Method of Measuring the Mössbauer Effect

The Mössbauer effect[1] is of great value because of the extremely high energy resolution it provides, but it is often very difficult to measure, because it may be very small (for example, about 0·07 × 10^{-2} per cent for zinc-67 in zinc metal[2]). Common values are about 1 per cent of the total absorption, and even these may be attained only at very low temperatures. A differential absorption of this order is very difficult to measure with precision, particularly at low temperatures, because the stability of the equipment must be exceptionally high. For these reasons, most of the detailed applications have involved the use of the 14·4-keV. line of iron-57, which gives about 14 per cent differential absorption at room temperature. The parent nuclide is cobalt-57, which is difficult to prepare; moreover, the internal magnetic fields in iron cause a hyperfine splitting, and the low energy (14·4 keV.) makes the radiation difficult to use. Further, very strong sources are needed, because the distance from source to counter is large and because the source is used for only a small proportion of the total time. Finally, the velocity of the source relative to the absorber varies (owing to the curvature of the path) and is known only to 10 per cent or so if a system similar to Mössbauer's original one is used.

Fig. 1 shows schematically a system designed to overcome these disadvantages. The phosphor *P* (of a scintillation counter) is placed inside an open-ended drum *D*, which bears the absorber (one, not two). The source *S* is mounted on a vibrating strip *V*. The axis of rotation of *D* lies below the line joining *S* to *P*, so the absorber has a known effective velocity relative to *S*. The drum (diameter 3 in.) is driven via a continuously variable gear; the velocity is swept evenly continuously through zero. The thick copper strip *V* is clamped at *C* and performs bending vibrations, thus causing the source to vibrate along the line *S–P* (a motor-driven cam provides the motion). The strip dips into liquid nitrogen. The lower edge of the drum also dips into liquid nitrogen. The alternating signal from the ratemeter is fed to a phase-sensitive detector, the output of which is the first derivative of the Mössbauer line. Fig. 2 shows a

True errors which would take into account argon loss are much greater—see text.

suggesting an affinity between Africa and the Seychelles. This would be consistent with the view that the islands represent a continental fragment left during the widening of the Indian Ocean.

Samples of hornblende from Mahé and other islands of the Archipelago have been received from Dr. B. H. Baker of the Ministry of Commerce, Industry and Communications, Mines and Geological Department, Nairobi. Work has begun on these, and upon basaltic material from typical oceanic islands in the Atlantic.

We are especially grateful to the Governor of the Seychelles for providing the samples on which the measurements were made. Also we wish to thank Dr. D. H. Matthews of the Department of Geodesy and Geophysics, Cambridge, for his help and interest in this work, and Dr. S. O. Agrell of the Department of Mineralogy and Petrology, Cambridge, for preparing thin sections of the rocks. We are indebted to the Department of Scientific and Industrial Research for financing the project, which is part of a programme of investigation into the geochronology of oceanic rocks.

Age Determinations of Rocks in the Lizard (Cornwall) Area

A PREVIOUS attempt to date the major geological events in the Lizard area[1] using the potassium–argon total volume method on biotites and muscovites gave a Caledonian age of 391 million years for the youngest intrusives, the Kennack Gneiss, but gave an anomalously younger age of 356 million years for the regionally metamorphosed Old Lizard Head Series. A series of independent measurements by Dodson[2] using the isotope dilution method gave a similar pattern with the younger age (350 million years) from muscovite from the Old Lizard Head Series and the older age (368 million years) from the Kennack Gneiss and also from biotite from the Landewednack Hornblende Schist, co-metamorphic with the Old Lizard Series. The differences between our results and those of Dodson are of the same magnitude evident in comparative measurements previously described[3].

Potassium–argon measurements have now been made on five hornblendes collected from the Kennack Gneiss (96392), the regionally metamorphosed Landewednack Hornblende Schist (96389, 96396) and the dynamothermal aureole of the peridotite (96394, 96395). The argon measurements were made by the method of isotope dilution. Potassium oxide was determined by six or eight measurements on different samples using the flame photometer. The standard deviations of these measurements are given in Table 1. Because of the low potassium content of the hornblendes the main source of error in the age values lies in the potassium oxide determinations.

The hornblende 96392 is from the same specimen of Kennack Gneiss that gave a 397-million year age from biotite. The two specimens of Landewednack Hornblende Schist are interbedded and co-metamorphic with the Old Lizard Head Series which gave an average age of 356 million years for muscovite. One hornblende (96396) gives an age agreeing with that of the Kennack Gneiss but the other (96389) gives an appreciably older age.

The two hornblendes from the metamorphic aureole of the peridotite have very different ages. No. 96395 is from the green-brown hornblende amphibolite assemblage at about 800 yards from the nearest peridotite outcrop. This gives an age (357 million years) compatible with the Caledonian ages previously described. No. 96394 is a brown hornblende from a band of hornblende–hypersthene–augite granulite immediately in contact with the peridotite. The brown hornblende gives a much greater age of 492 million years, more in harmony with the geological evidence that the regional metamorphism and peridotite intrusion are much earlier than the intrusion of the basaltic dykes and Kennack Gneiss.

The interpretation placed on these results is that the Caledonian age of 360–390 million years is a true one for the intrusion of Kennack Gneiss. This was also a period of partial or complete loss of argon for pre-existing metamorphic assemblages. The specimen of rather massive Landewednack Hornblende Schist and particularly the hornblende granulite interbanded with the peridotite at the peridotite margin may have been partly insulated from the Caledonian effects and reflect partial argon loss from Pre-Cambrian or Cambrian minerals. Hercynian thrusting may also have caused loss of argon, particularly from micas in the flat-foliated, less competent Old Lizard Head Series.

The present results are significant as further evidence that hornblendes of low potassium content can give meaningful ages in determinations by the potassium–argon method.

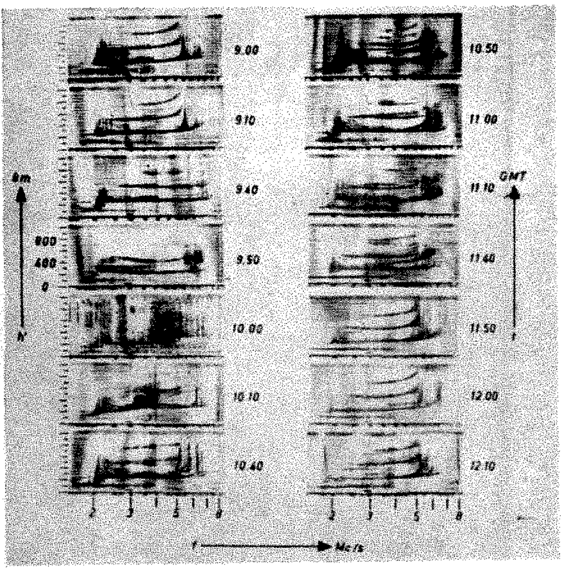

Fig. 3. Ionograms obtained at Sodankylä on October 31, 1961, showing a disturbance caused by the round-the-world ionospheric waves

On October 31, at 8.29.27 G.M.T., another atomic explosion occurred in Novaya Zemlya at a distance of 1,190 km. The deflexion of the microbarograph due to this explosion was about a third of the deflexions due to the round-the-world waves of the big explosion. Further, the ionospheric disturbance due to the latter ones was more than one hour too late to be originated from the smaller explosion. It can, therefore, be said that the smaller explosion had no detectable effect on the ionosphere.

Potassium-Argon Age Determinations on Granite from the Island of Mahé in the Seychelles Archipelago

The Seychelles Archipelago is situated in the Indian Ocean some 1,100 miles to the east of Mombasa. It is made up of nineteen islands and a number of islets of which all but two are granitic in composition. The only two coral islands in the group are Bird and Denis, which lie at a distance of about sixty miles north of Victoria, Mahé. Mahé itself is the largest of the islands, being seventeen miles long and up to seven miles wide. Rugged peaks of granite rise to a height of almost 3,000 ft. above sea-level and show marked erosion features. Praslin, Silhouette and Digue are the other main granitic islands of the group.

Throughout the islands, the most common rock type is pink or grey amphibolite granite. Syenite occurs on Longue Island and in the southern part of Silhouette. In various localities the plutonics are intruded by dykes of varied composition.

Sedimentary rocks are absent, though the occurrence of andalusite-hornfels on the islands of Silhouette, Cerf and Stag[1,2] may indicate that clay slates once existed.

The granitic islands lie in the centre of an extensive submarine platform that is surrounded by depths of more than 1,000 fathoms and completely separated both from the Carlsberg Ridge and from Madagascar. By any criteria other than petrographic, the islands are of oceanic type.

The age of the group is not known, but the degree of erosion suggests prolonged action by the agents of weathering. Coral fragments are to be found cemented on to the granite at heights varying between 10 and 30 ft. above low-tide level. In addition to this evidence of recent elevation, Gardiner[3] considers that a more ancient uplift of some 200 ft. occurred.

Age determinations have been carried out on samples of pink and grey granite from the island of Mahé. Owing to the small amount of biotite present in the particular samples used in this work and its partially decayed state, preliminary measurements were made on samples of the whole rock. Most of the potassium in the material is situated in the feldspars, consequently owing to loss of argon by diffusion, a total rock determination would yield an age less than the true value. However, these measurements yielded an average minimum age for the rock of 515 million years. The close agreement of the total rock ages of the pink and grey granites (Table 1) does suggest that they were formed simultaneously.

A few grams of altered biotite were separated from the pink granite in an attempt to determine its absolute age. This result is shown in Table 1 and substantiates the preliminary results.

The total-volume method was used in age determinations on the whole rock and the technique of isotope dilution used in the measurement of the biotite sample.

Owing to the coarse and variable nature of the granite it is possible that the samples used in the potassium oxide analyses of the total rock might not have been identical to those used in the argon measurements. In view of this, the combined errors arising from uncertainties in content of potassium oxide and volume of argon measurement are estimated at ± 5 per cent. Experimental errors are, however, insignificant compared with those caused by loss of argon from the feldspars. Experience has shown that 30 per cent of the argon can easily have been lost by diffusion. Though the biotite is partially altered, losses should not be of this magnitude. In Table 1 the apparent ages together with their estimated experimental errors are given. Errors arising from loss of argon cannot be accurately evaluated and have not been included.

From these measurements it is concluded that Mahé Island and most probably all the granitic islands of the Seychelles Archipelago came into existence during the very late Pre-Cambrian. Most oceanic islands are considered to be younger than Mid-Cretaceous, consequently the Seychelles are out of place chronologically and petrologically.

It is interesting to note that a large number of minerals from the continent of Africa have ages around 630 million years[4]. If the age yielded by the biotite sample is a true one, it could be evidence

GEOPHYSICS

Round-the-World Sound Waves produced by the Nuclear Explosion on October 30, 1961, and their Effect on the Ionosphere at Sodankylä

The heavy nuclear explosion on October 30, 1961, at 8.33.33 G.M.T. at a distance of 1,160 km. in Novaya Zemlya (presumably at tropospheric heights) was recorded at Sodankylä by means of a seismograph, a microbarograph, a magnetograph, and a vertical incidence ionosonde. The deflexion of the microbarograph took place at 9.42 G.M.T. with an amplitude of about ± 1 mb. The ionosonde showed a sudden, heavy disturbance in the *E* and *F* regions at 9 G.M.T., that is, 42 min. before the deflexion of the microbarograph (Fig. 1).

On October 31, the microbarograph again showed two very distinct and strong deflexions, namely, at 18.32 and 21.28 G.M.T. These deflexions are interpreted as being caused by round-the-world waves due to the same nuclear explosion, one being propagated in the backward, the other in the forward, direction (Fig. 2). The mean velocity deduced from these round-the-world waves is 311 m./sec. and is in good agreement with calculations based on mean atmospheric conditions below the stratopause. The wave-lengths in the recorded wave-trains lie between 198 and 58 km., and the waves are supposed to have been guided in the spherical shell between the ground and the stratopause.

Because there were no pronounced magnetic effects during the ionospheric disturbance, it seemed to be clear that the latter was not caused by excessive ionization but by a shock-wave passing over Sodankylä at ionospheric heights. This shock-wave would lose its excessive velocity and be propagated later as a sound wave in the temperature minimum between the stratopause and the lower thermosphere. If the waves are long, of the same order of magnitude as those measured on the ground, and if the formula which is giving the absorption loss[1] and which is normally applied to shorter wave-lengths will hold approximately for these wave-lengths, they can be propagated around the world without excessive attenuation. On the other hand, the intensity of the returning waves in the vicinity of the explosion site is greatly increased by focusing. Therefore, it seems reasonable to assume that these waves are strong enough to cause a detectable ionospheric effect when passing over Sodankylä.

The velocity of sound waves at ionospheric heights was estimated using rocket data[2]. The mean value obtained for the velocity was 420 m./sec., which is equivalent to round-the-world travelling time of 27 hr. On the other hand, according to the estimation mentioned above, the attenuation of such a sound wave travelling 40,000 km. and having a wave-length of 200 km. does not exceed 20 db. below heights of 150 km.

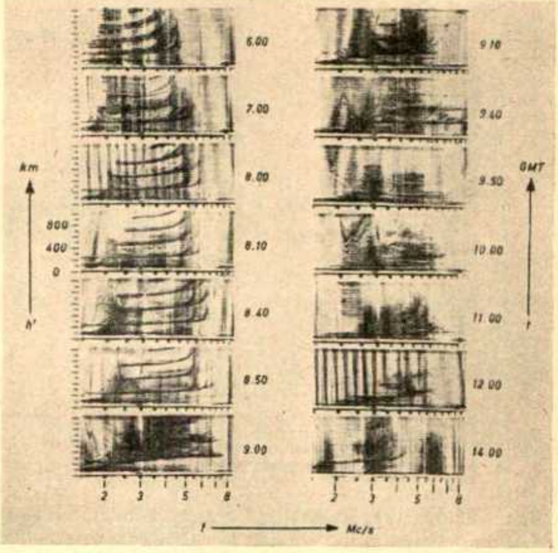

Fig. 1. Ionograms obtained at Sodankylä on October 30, 1961, showing an ionospheric disturbance caused by the nuclear explosion in Novaya Zemlya

The expected effects on the ionosphere are, indeed, to be seen on the ionograms (Fig. 3) at 9.50–11.40 G.M.T. on October 31. Although the ionograms are not completely continuous with time, we suppose that both the forward and backward propagated waves exist. This is because of the special shape of some of the oblique reflexions due to the slow sweeping speed of 4 min. over the frequency-range shown. We think that the end of the north-eastward travelling wave-train is to be seen on the ionogram at 10.50 G.M.T., whereas the end of the south-westward travelling one is to be seen on the ionogram at 11.40 G.M.T.

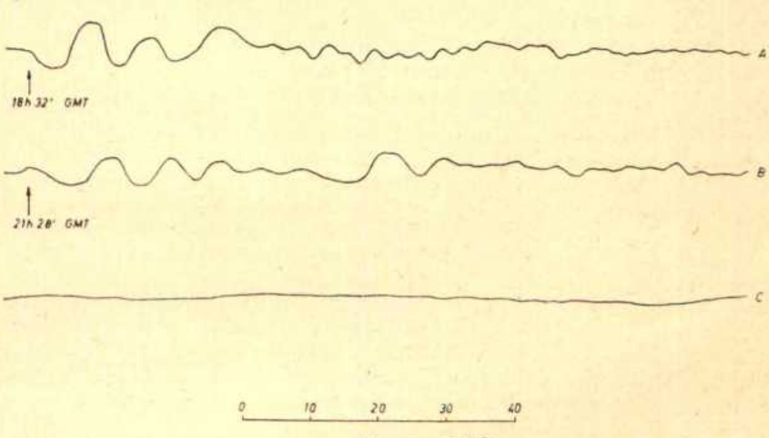

Fig. 2. Recordings of the microbarograph at Sodankylä on October 31, 1961. *A* and *B* are the deflexions of the backward and forward waves, respectively. *C* is a trace obtained under normal conditions. Pressure increases upwards

Table 3 THE FIVE TYPES OF STEP-REACTION INVOLVED IN THE BIOSYNTHESIS OF CAROTENOIDS IN PURPLE BACTERIA

* R = H or CH_3

dehydrogenations across a C—C bond, like those required by structures X and XI, are exceedingly common enzymatic reactions

The scheme outlined in Fig 1 supposes a total of 15 step-reactions subsequent to phytoene These 15 reactions can be grouped into five different types, depicted diagrammatically in Table 3 Each type of reaction is defined by two parameters (*a*) the chemical nature of the change that occurs, and (*b*) the structure of the molecule immediately adjacent to the site of attack In principle, a total of five enzymes might therefore be sufficient to catalyse all the reactions shown in Fig 1 The biological evidence, suggests, however, that the actual number is somewhat greater In the genus *Rhodospirillum*, *Rhodospirillum molischianum* produces only lycopene and rhodopin, *Rhodospirillum photometricum* produces lycopene, rhodopin, rhodovibrin and anhydro-rhodovibrin, and *Rhodospirillum rubrum*, all the carotenoids of the *A* group These differences can be accounted for enzymatically only by the supposition that specific enzymes catalyse the two similar successive dehydrogenations of type 2 involved in this sequence Both these enzymes are lacking in *Rhodospirillum molischianum*, one is present in *Rhodospirillum photometricum* and both are present in *Rhodospirillum rubrum*

The divergence of biosynthetic pathways subsequent to the formation of neurosporene, which leads in most purple bacteria to the exclusive formation of either group *A* or group *B* pigments, implies that the dehydrogenation of neurosporene to lycopene is enzymatically distinct from the preceding dehydrogenations which result in the formation of neurosporene from phytoene, even though it also belongs to type 1 On the other hand, the accumulation patterns observed in mutants rather strongly suggest that the three dehydrogenations which result in the conversion of phytoene to neurosporene may all be catalysed by a single enzyme Both in purple bacteria and in other organisms synthesizing carotenoids, mutants which accumulate phytoene alone have been frequently isolated Such mutants must have lost the enzyme required to convert phytoene to phytofluene But mutants which can be interpreted as having lost the enzyme that converts phytofluene to ζ-carotene, or ζ-carotene to neurosporene, have never been found When a mutational block leads to the accumulation of phytofluene and ζ-carotene, these substances are invariably accompanied by much larger amounts of more oxidized carotenoids (for example, neurosporene and chloroxanthin in the green mutant of *Rhodopseudomonas spheroides*) These otherwise puzzling facts become readily intelligible on the hypothesis that all the dehydrogenations between phytoene and neurosporene are catalysed by the same enzyme, loss of this enzyme necessarily resulting in the accumulation of phytoene alone

A full account of the chemical investigations by one of us (S L J) on the structures of the group *A* carotenoids and a further discussion of the present topic will be published elsewhere

We wish to acknowledge the kindness of Prof B C L Weedon in communicating to us the chemical structures of certain of the carotenoids discussed, prior to their publication

Note added in proof The biosynthetic scheme shown in Fig 1 predicts the existence of an intermediate between rhodopin (IX) and anhydro-rhodovibrin (XI), since this conversion requires both a dehydrogenation of type 2 and a methylation The expected intermediate, 3,4-dehydro-rhodopin, has recently been discovered by one of us (S L J) in *Rhodopseudomonas palustris* The structure of this new group *A* carotenoid has been unequivocally established by the determination of its nuclear magnetic resonance spectrum (Jackman, L M, and Jensen, S L, *Acta Chem Scand*, in the press) The position of the chromophore in 3,4-dehydrorhodopin provides further support for the assignment of structures X and XI to rhodovibrin and anhydrorhodovibrin, respectively

(XVIII) R=H, R'=

(XVIIIa) R=CH_3, R'=

When the wild-type of *Rhodopseudomonas spheroides* is cultivated under semi-aerobic conditions, its carotenoid composition changes markedly from that characteristic of anaerobic (photosynthetic) cultures[7] Pigments *Y* and OH-*Y* virtually disappear, the major carotenoids are spheroidenone and OH-*R*, accompanied by smaller amounts of a very highly unsaturated carotenoid which has been termed *P*512 (ref 1) The adsorptive properties reported for this carotenoid[1,9] suggest that it contains at least one hydroxyl group The positions of the absorption maxima in visible light fit with the assumption of 12 carbon-carbon double bonds and a keto group in conjugation The biosynthesis of *P*512 can be interpreted as resulting from the dehydrogenation of OH-*R* or spheroidenone by a reaction of the type characteristic of the phytoene-lycopene sequence, suggesting structure XVIII or XVIII*a* for this carotenoid.

We plan to investigate further the chemical structures of OH-*Y*, OH-*R* and *P*512

Conclusions

The complete scheme which we propose for the biosynthesis of the carotenoids of the purple bacteria is shown in Fig 1 It should be noted that in this scheme structures X and XI have been employed for rhodovibrin and anhydro-rhodovibrin, respectively, even though the chemical data now available do not exclude structures X*a* and XI*a* The preference for X and XI rests on the fact that these structures make it possible to formulate the conversion of lycopene to anhydro-rhodovibrin, and of anhydro-rhodovibrin to spirilloxanthin, as reactions strictly analogous to the conversion of neurosporene to pigment *Y* Furthermore, α,ω-dehydrogenations of the type which must occur in the biosynthesis of spirilloxanthin assuming structures X*a* and XI*a* are not known to occur as enzymatic reactions, whereas

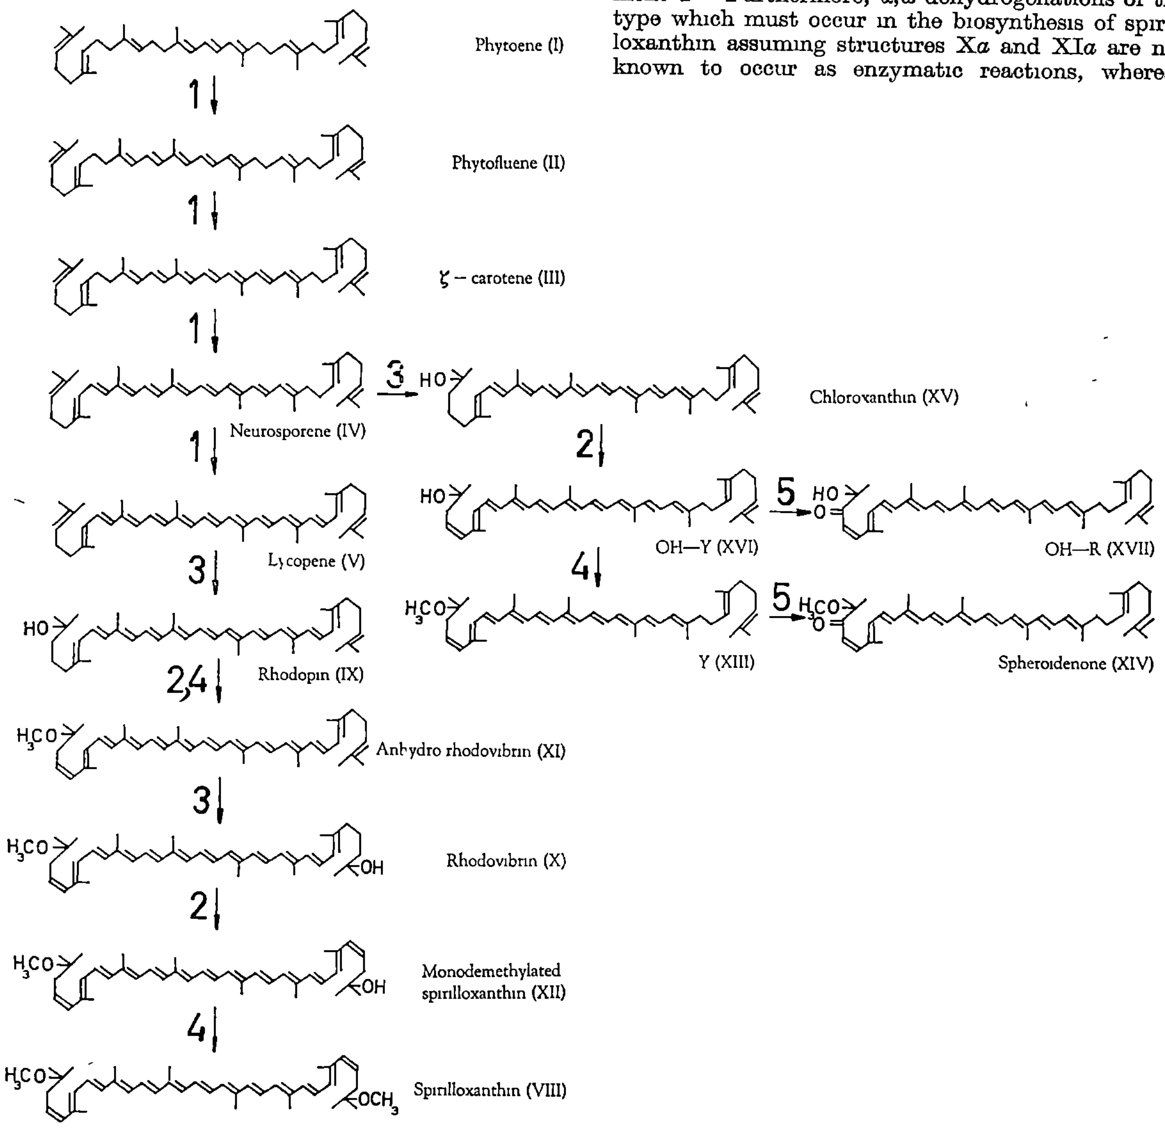

Fig 1 Structural scheme for the pathway of carotenoid biosynthesis in purple bacteria

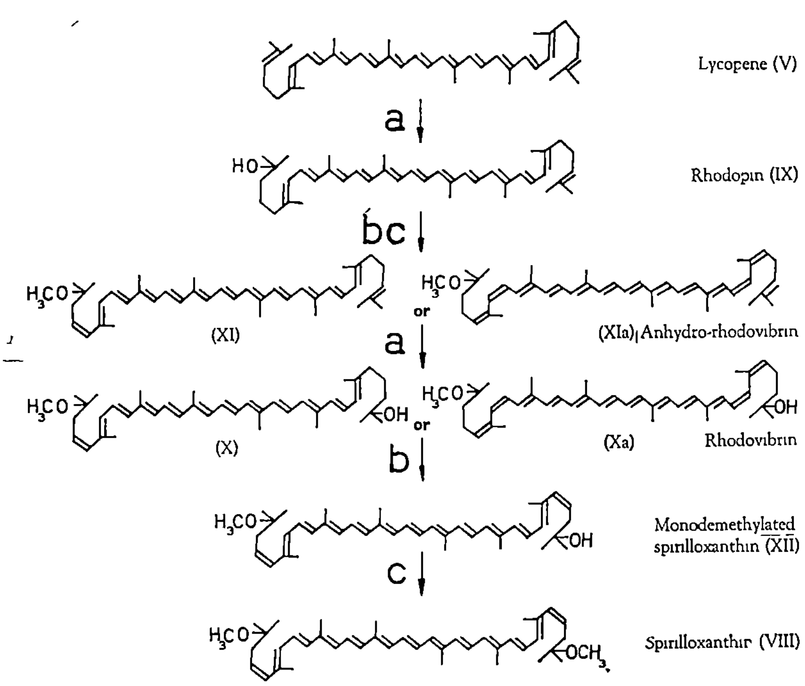

(VIII)[26–28], and to the demonstration that the monohydroxylycopene formed in *Rhodospirillum rubrum* is identical with rhodopin, not with lycoxanthin (VI). Structure IX has been assigned to rhodopin[29,30]. Furthermore, the structures of the pigments known as OH-*P*481, *P*481 and OH-spirilloxanthin have been largely determined. OH-*P*481 is identical with rhodovibrin, and has either structure X or structure X*a* (ref. 31). *P*481 (anhydro-rhodovibrin) has either structure XI or structure XI*a* (ref. 32). In the case of these two pigments, the uncertainty concerns the exact position of the chromophore in the molecule. OH-spirilloxanthin is a monodemethylated spirilloxanthin (XII) (ref. 28).

In the light of these chemical facts, a simple and consistent interpretation of the biosynthetic transformations between lycopene and spirilloxanthin can now be offered[32]. These transformations involve three different types of chemical reactions, each of which takes place twice in the overall sequence:

(*a*) The hydroxylation step: addition of water to an isopropylidene double bond, with formation of a tertiary alcohol.

(*b*) The dehydrogenation step: introduction of an additional double bond in conjugation with the already existing chromophore, either at the same side as the hydroxyl group (assuming formulæ X and XI for rhodovibrin and anhydro-rhodovibrin) or by α,ω-dehydrogenation (assuming formulæ X*a* and XI*a* for the two compounds in question). For reasons of biochemical analogy which will be shortly discussed, we prefer the first formulation and thus favour formulæ X and XI.

(*c*) The methylation step: methylation of a tertiary hydroxyl group.

The initial reaction which leads to the formation of the group *A* pigments is a dehydrogenation: the conversion of neurosporene to lycopene. This reaction is not a dehydrogenation of type *b*, but is analogous rather to the successive dehydrogenations which result in the conversion of phytoene to neurosporene.

Biosynthesis of the Group *B* Carotenoids

Goodwin, Land and Sissins[8], who first investigated the chemical structure of pigment *Y* and spheroidenone (pigment *R*), showed that they were monomethoxy compounds, and that spheroidenone had a conjugated keto group. The actual structures which they proposed[7,33] were, however, incorrect. Definitive structures for pigment *Y* (XIII) and spheroidenone (XIV) have recently been established by Barber, Jackman, Weedon and Yokoyama[34]. Pigment *Y* can be visualized as consisting of half a spirilloxanthin molecule (VIII) coupled with the more saturated half of the neurosporene molecule (IV). This, in turn, suggests that a sequence of reactions similar to those operative in spirilloxanthin synthesis must occur in the synthesis of pigment *Y* from neurosporene. Structurally speaking, this would require the formation of compounds XV and XVI as intermediates.

Structure XV has recently been suggested for chloroxanthin by Barber, Jackman, Weedon and Yokoyama[34]. Chloroxanthin, first characterized by Nakayama[9], is a monohydroxy derivative of neurosporene that accumulates together with neurosporene in the green mutant of *Rhodopseudomonas spheroides*, which is totally blocked in the synthesis of pigment *Y* and spheroidenone.

In the wild-type of *Rhodopseudomonas spheroides* grown anaerobically in the light, pigment *Y* and spheroidenone are always accompanied by smaller amounts of related monohydroxy compounds. The properties so far reported for OH–*Y* (refs. 7 and 9) are in accord with those which can be predicted for structure XVI. We therefore suggest that OH–*Y* is non-methylated and is the immediate biosynthetic precursor of *Y*. A similar chemical relationship can be postulated between speroidenone and OH–*R*, in which case the latter should possess structure XVII. The limited chemical data available[7,9] are in accord with such a supposition.

(XVI)

is phytoene[7], the specific site of the enzymatic defect is thus reasonably interpreted as lying at the step between phytoene and phytofluene

The biosynthetic origin of the group *B* pigments has been investigated in *Rhodopseudomonas spheroides*, from which a series of mutants with specific blocks in carotenoid synthesis has been isolated The patterns of accumulation in these mutants (Table 2) are most readily interpreted in terms of the following sequence

$$\text{phytoene} \rightarrow \text{phytofluene} \rightarrow \zeta\text{-carotene} \rightarrow \left\{ \begin{array}{l} \text{neurosporene} \\ \text{chloroxanthin} \end{array} \right\} \rightarrow Y \rightarrow \text{spheroidenone}$$

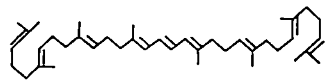
The biochemical data accordingly suggest that the pigments of groups *A* and *B* are synthesized from a common series of more saturated carotenoids originating with phytoene, the specific pathways diverging from one another subsequent to the formation of neurosporene In support of the hypothesis of a common origin for the pigments of both groups, it should be added that traces of neurosporene, ζ-carotene and phytofluene can be found in exponentially growing cells of the wild types of both *Rhodospirillum rubrum* and *Rhodopseudomonas spheroides*[4,7]

The biological experiments which led to these interpretations of carotenoid synthesis in purple bacteria were carried out several years ago At that time, there were many uncertainties and some misconceptions concerning the chemical structures of the compounds involved Consequently, it was not then possible to formulate in chemical terms the postulated reaction sequences, or to establish the chemical nature of the individual step-reactions. These uncertainties and misconceptions concerning carotenoid structure have been largely eliminated by recent chemical work, which reveals that the earlier biological data in fact conform with a rather simple and chemically intelligible biosynthetic scheme We shall consider in turn the nature of the common primary step-reactions and of the specific step-reactions which lead to the group *A* and group *B* pigments

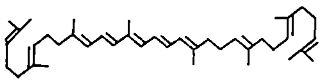
The Common Primary Step-Reactions

The structure of phytoene (I) was well established by the work of Rabourn and Quackenbush[12] The same workers afterwards assigned structures to phytofluene (II) and ζ-carotene (III)[13,14], although the chemical evidence for these structures has not yet been published Zechmeister[15] also recently suggested structure II for phytofluene Structures I, II and III for these carotenoids have been confirmed in an elegant fashion by Davis, Jackman, Siddons and Weedon[16] Neurosporene was long considered to be identical with 5,6,5′,6′-tetrahydrolycopene, synthesized by Eugster, Linner, Trivedi and Karrer[17], and thus to be a structural isomer of ζ-carotene (III) The improbability of an isomeric relationship between ζ-carotene and neurosporene in the light of the chemical evidence available had been pointed out by several authors[18,19], but definite proof that neurosporene is a dihydrolycopene with structure IV has only recently been furnished by Davis, Jackman, Siddons and Weedon[16]

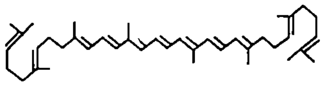
Phytoene is characterized by the possession of a centrally located chromophore with 3 conjugated double bonds, and of 6 isolated double bonds, the molecule thus possesses complete bilateral symmetry



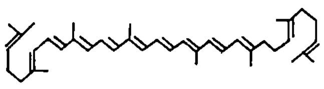
Phytoene (I)



Phytofluene (II)



ζ – carotene (III)



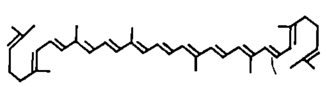
Neurosporene (IV)

The successive formation of phytofluene, ζ-carotene and neurosporene from phytoene evidently involves a series of stepwise dehydrogenations at each step, a new double bond is introduced alternatively to the left and to the right side of the phytoene chromophore Each double bond so introduced brings into conjugation one of the previously isolated double bonds, and the length of the chromophore is accordingly increased by two conjugated double bonds at each step The biosynthesis of neurosporene from phytoene therefore proceeds by three successive dehydrogenations, identical in mechanism and differing from one another only in the specific points on the polyene chain at which they take place

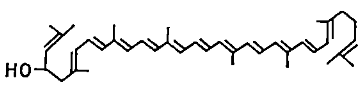
A reaction sequence of this type was in essence first proposed by Zechmeister[20], on the basis of chemical considerations, to account for the biological origin of the coloured carotenoids This hypothesis was further elaborated by Porter and Lincoln[21], who used it to explain the genetic and biochemical data concerning carotenoid synthesis in tomato fruits The so-called 'Porter–Lincoln sequence', which is in fact the only coherent general hypothesis ever advanced to explain the biological formation of coloured carotenoids, was long treated with scepticism by most workers in the field (see, for example, refs 22 and 23) Such scepticism can no longer be justified

Biosynthesis of the Group *A* Carotenoids

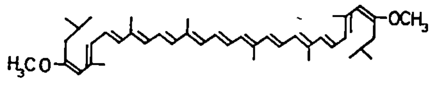
At the time when the biosynthetic pathway from lycopene to spirilloxanthin was determined in *Rhodospirillum rubrum*, the structures of three members of the sequence were assumed to be established lycopene (V)[3], lycoxanthin (VI)[8,24] and spirilloxanthin (VII)[25]



(V)



(VI)



(VII)

However, recent chemical investigations have led to a revision of the structure of spirilloxanthin induced by electrical stimulation of reticular formation, involve (at least as a component of a more complex mechanism) the breakdown of high-energy phosphorus compounds Triggered by the impulses generated by reticular neurones it sets in motion the processes leading to lactic acid formation Our results confirmed the finding of previous workers[4] that the brain lactic acid does not rapidly disappear from the tissue when once it has been formed

From these considerations it follows that, unless it is believed that changes produced by electrical stimulation of brain stem reticular formation in our experiments are not of a physiological nature, it must be inferred that physiological processes resulting from an increased functional activity of reticular neurones (such as arousal or increased attention) are associated with increased glycolytic activity and the liberation of the lactic acid in the brain

We thank Dr R M C Dawson, Institute of the Department of Animal Physiology, Cambridge, for kind advice regarding the method of lactic acid estimation

BIOSYNTHESIS OF CAROTENOIDS IN PURPLE BACTERIA: A RE-EVALUATION BASED ON CONSIDERATIONS OF CHEMICAL STRUCTURE

By SYNNØVE LIAAEN JENSEN, DR GERMAINE COHEN-BAZIRE and PROF R Y STANIER

Institute of Organic Chemistry, Technical University of Norway, Trondheim,
and Department of Bacteriology, University of California, Berkeley, California

THE photosynthetic apparatus of purple bacteria contains a distinctive array of carotenoid pigments they are aliphatic, and mostly bear methoxyl groups Five main pigments, together with their monohydroxy derivatives, have been found in the species so far examined lycopene, *P*481 (anhydrorhodovibrin), spirilloxanthin, pigment *Y* and spheroidenone (formerly known as pigment *R*) On the basis of their biological distribution, these ten pigments can be subdivided into two main groups (Table 1) Some species of purple bacteria contain exclusively pigments of the lycopene, *P*481 and spirilloxanthin types (group *A* pigments), others, exclusively those of the *Y* and spheroidenone types (group *B* pigments) These regularities in distribution in themselves strongly suggest that the pigments of groups *A* and *B* represent the products of two divergent biosynthetic pathways Stoichiometric interconversions of pigments belonging to each group have been demonstrated to take place in certain circumstances within the bacterial cell, and this and the nature of the observed conversions establish unequivocally two sets of biosynthetic interrelationships[4-6]

$$\text{lycopene} \rightarrow P481 \rightarrow \text{spirilloxanthin, and}$$
$$Y \rightarrow \text{spheroidenone}$$

In *Rhodospirillum rubrum*, synthesis of all group *A* pigments can be suppressed by bacterial growth in the presence of an appropriate concentration of diphenylamine In these circumstances, there is a massive intracellular accumulation of carotenoids more saturated than lycopene (phytoene, phytofluene, ζ-carotene, neurosporene) After removal of the diphenylamine, these reduced carotenoids can be converted within the cell to the typical group *A* pigments The analysis of the diphenylamine effect in *Rhodospirillum rubrum* has permitted the formulation of the following biosynthetic sequence for the group *A* pigments[4]

$$\begin{array}{c}\text{phyto-}\\\text{fluene}\end{array} \rightarrow \begin{array}{c}\zeta\text{-caro-}\\\text{tene}\end{array} \rightarrow \begin{array}{c}\text{neuro-}\\\text{sporene}\end{array} \rightarrow \left.\begin{array}{l}\text{lycopene}\\\text{OH-lycopene}\end{array}\right\} \rightarrow$$
$$P481 \rightarrow \text{OH-}P481 \rightarrow \left\}\begin{array}{l}\text{spirilloxanthin}\\\text{OH-spirilloxanthin}\end{array}\right.$$

So far, only one mutant of *Rhodospirillum rubrum* with a specific block in carotenoid synthesis has been found The only carotenoid produced by this mutant

Starting from these investigations and the well-established role of the reticular formation in the regulation of the states of wakefulness and sleep, the present investigation was carried out to find out if similar biochemical changes take place in the brain following electrical stimulation of the brain-stem reticular formation and if they could be correlated with concomitant changes in electrical activity

Young rats of 50–90 gm anæsthetized with 'Nembutal' (50 mgm /kgm body-weight) were used in the experiments Recording electrodes were placed on the frontal and parietal cortex A fine stimulating electrode (0 01 in diameter) was inserted stereotaxically in the brain-stem reticular formation according to co-ordinates based on measurements previously made on several animals of similar age and size The operative procedure was completed in 10 min after initiation of anæsthesia in all experiments Stimulating and recording was programmed in such a way as to permit immersion of the animals into liquid air exactly at the end of the twentieth minute after 'Nembutal' injection Thus, the period of anæsthesia was maintained constant in all the experiments Electrical stimuli (0 3 m amp , 300 cycles/sec and 0 25 m sec pulse duration), delivered by a Grass stimulator model 4*S*, were given for two periods of 10 sec , with an interval of 5 sec between the two stimulations The electrocorticogram was recorded throughout the experiment using a Reega Alvar apparatus This provided an index of the blood and oxygen supply to the brain during the experiment Details of the stimulation and recording technique are published in ref 3

Rats were divided into eight groups (each consisting of at least seven animals) Rats from the first (control) group received only an injection of 'Nembutal', those from the second (control) group were placed in the stereotaxic instrument, incision was made and holes drilled in the skull, the third (control) group consisted of rats, with cortical and reticular electrodes inserted, which were not subjected to stimulation Animals belonging to the fifth, sixth, seventh and eighth group were stimulated as described and dropped in the liquid air 30 sec , 1 min , 3 and 5 min respectively, after cessation of electrical stimulation In order to secure rapid fixation of biochemical changes and prevent post-mortem glycolysis, animals were killed by immersion in the liquid air Reasons for freezing the whole animal have been described (ref 4). To facilitate dissection, the frozen animals were immediately transferred into a deep-freezer at – 20° C Rapidly dissected with cooled instruments, brains (sectioned just in front of the cerebellum) were dropped in the liquid air and powdered in a previously cooled crusher Lactic acid was estimated according to the method of Friedemann *et al.* with modifications introduced by other authors[5]

The results are illustrated in Fig 1 In the first (control) group of animals, killed after being in anæsthesia for 20 min , the lactic acid content ranged from 6 5 to 10 5 mgm per cent with a mean of 8 9 (broken line in Fig. 1) These figures are in agreement with values obtained by other authors under similar conditions[4] Estimations of the lactic acid content of the brain of rats comprising the second and third (control) group of animals gave somewhat higher values than those of the first group (12 0 and 12 5 mgm. per cent respectively—full line in Fig 1) This showed that fixing the animal into the stereotaxic apparatus and the operative procedure used, already raised to some extent the lactic acid content of the brain It is conceivable, therefore, that this level should be taken as a basis for comparing values obtained after electrical stimulation As seen in Fig 1, electrical stimulation of brain stem reticular formation was consistently found to be followed by a rapid and significant increase of the lactic acid content of the brain ($P > 0\ 001$ with Fisher's t test) No such high values were obtained following focal stimulation of cerebral cortex under identical conditions or even after strong hippocampal after-discharge produced by insertion of electrode into this structure Experiments in which the period between the cessation of electrical stimulation and immersion of animal into the liquid air was varied from 30 sec to 5 min (Fig 1) showed that this increase was of short duration, followed by a return of the lactic acid within the limits of control variations 5 min after discontinuing the stimulation

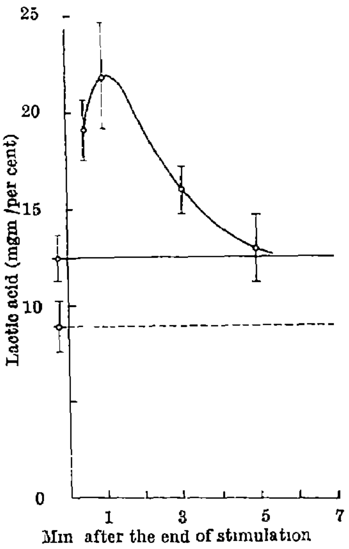

Fig 1

It should be pointed out that raising the lactic acid outlasted the transient desynchronization of the electrocorticogram When increase of lactic acid was at a peak (that is, between 30 sec and 1 min after discontinuing the stimulation) the pre-stimulation type of electrical activity was usually recorded

Formation of the lactic acid in the brain under normal physiological conditions has been demonstrated by Gibbs *et al* Experiments of Richter and Dawson showing that the lactic acid content of the brain is lowered in normal sleep and increased in emotional excitement provided further evidence that the rate of lactic acid formation varies with the functional activity of the brain[4] In another series of experiments these authors reported that electrical stimulation of the brain produces a rapid fall in the phosphocreatine content and transient rise in the hexose phosphate fraction followed by their return to normal level 15–45 sec after electrical stimulation, indicating the dynamic balance between the breakdown and re-synthesis of high-energy phosphate bonds[7]

Results reported in the present article also suggest that biochemical events, underlying the 'dynamogenesis' or increased functional activity of the brain

Table 3*

* Refs 11–15

but do not destroy the antithrombin activity of normal cerebrospinal fluid This activity is not adsorbed by barium sulphate or destroyed by heating (45°, 1 hr), but disappears after addition of ether or heating at 75° for 10 min and at 100° for 1 min

The considerable antithrombin activity of the pathological cerebrospinal fluid is due either to the increase of physiological antithrombin or to the appearance of an abnormal antithrombin(s ?) The last possibility is even more probable because the pathological antithrombin is adsorbed on barium sulphate which does not adsorb the physiological antithrombin of cerebrospinal fluid The pathological antithrombin activity seems to be higher in the acute phase of inflammatory (meningitis) than in chronic neurological diseases (especially degenerative diseases, for example, progressive palsy) and to decrease with improvement of clinical and laboratory signs The relationship between the antithrombin of pathological cerebrospinal fluid and antithrombin I and VI, trypsin (present in inflammatory cerebrospinal fluid)[10] or other proteo-fibrino(geno)lytic agents can be established only after further investigations Contrary to the behaviour of blood antithrombins, the pathological antithrombin of cerebrospinal fluid is adsorbed on barium sulphate and has a progressive action (Table 3)

The question as to where the antithrombin of normal and pathological cerebrospinal fluid is formed and how it enters the fluid cannot be answered Also the significance of, and part played by, the normal and pathological antithrombin of cerebrospinal fluid remain unknown The investigations on the hæmostatic (especially antithrombin) activity of normal and pathological fluid can possibly help the diagnosis, differentiation and prognosis of certain neurological diseases.

The investigations were supported by the Rockefeller Foundation and by the Polish Institute of Sciences in the United States

EFFECTS OF ELECTRICAL STIMULATION OF RETICULAR FORMATION ON THE LACTIC ACID CONTENT OF THE RAT BRAIN

By Lj MIHAILOVIĆ, Lj KRŽALIĆ and D. CVETKOVIĆ

Institute of Pathological Physiology, Medical School, University of Belgrade

IT is customary, especially in the literature on electrophysiology, to speak about the 'activating', 'energizing', or 'dynamogenic' action of the brain-stem reticular formation on the electrical activity of the cerebral cortex Since the pioneer work of Moruzzi and Magoun[1], a great deal of information has been accumulated concerning the electrical manifestations of this activating process and its neuronal mechanism However, little is known about the metabolical correlates of this activation, that is, about the biochemical events triggered by impulses from reticular neurones It is generally assumed that any form of stimulation or departure from the resting state might start glycolytic processes, with the liberation of inorganic phosphorus and lactic acid It has been reported that the metabolical activity of the brain is increased in trauma, shock, convulsions and emotional excitement and reduced in anæsthesia and sleep[2] blood[9]. Gohr and Scholl[1] found in cerebrospinal fluid an inhibitor of thrombin generation which has no effect on the already generated thrombin. They denied any identity between this inhibitor and heparin, while Kafka[2-4] denied the existence of an antithrombin in cerebrospinal fluid at all.

In spite of the last negative statements we decided to re-investigate the problem of the antithrombin activity of normal and pathological cerebrospinal fluid.

(1) The cerebrospinal fluid was collected by lumbar puncture and centrifuged for 10 min. at 3,000 r.p.m. in order to sediment and eliminate the morphological elements. The determinations were performed after storing cerebrospinal fluid for 6 hr. at 4° C. (2) The primary solution of thrombin ('Thrombofort'—Richter plus distilled water) was diluted with veronal–acetate buffer in equal volumes in order to obtain a secondary solution. Only a part of the primary solution was used to prepare the secondary one, which allowed us to standardize the activity of the first thrombin solution. 0.2 ml. of the secondary solution must clot 0.2 ml. of oxalated deprothrombinized plasma within 30 ± 2 sec. (3) Deprothrombinized plasma was prepared from a pooled oxalated plasma from at least five blood-donors by shaking for 10 min. with barium sulphate (1 : 10) and subsequent centrifugation. This plasma, free from factors II, VII, IX and X, and containing factors V, VIII and XI (plasma thromboplastin antecedent), did not clot for at least 15 min. after the addition of equal volumes of thromboplastin and *M*/40 solution of calcium chloride.

To determine thrombin inactivation 0.4 ml. of the primary thrombin solution was mixed with 0.4 ml. of cerebrospinal fluid. Immediately, 0.2 ml. of this mixture was added to 0.2 ml. of oxalated deprothrombinized plasma. The coagulation time of the mixture was determined. The determination was carried out again after a 10- and 20-min. incubation of thrombin solution with cerebrospinal fluid. In a control reaction 0.2 ml. of veronal–acetate buffer (*p*H 7.35) was used instead of cerebrospinal fluid. All determinations were performed at room temperature.

The first group of experiments concerned twenty specimens of fluid showing no pathological changes in the routine laboratory tests (protein, globulin, sugar and chloride levels, pleocytosis, Nonne-Apelt, Weichbrodt and Pandy reactions). Table 1 shows that after 10- and 20-min. incubation the thrombin activity of the experimental mixture decreases slowly and progressively in the presence of normal cerebrospinal fluid. A certain tendency to a greater prolongation of the coagulation time in the presence of a higher concentration of proteins appeared, but was neither stable and repeatable nor statistically significant. The comparative investigations showed that the antithrombin of normal cerebrospinal fluid is considerably weaker than the antithrombin of blood and of pathological cerebrospinal fluid. Toluidine blue (0.05 ml. of a 2.5 mgm./ml. concentration) and protamine sulphate (0.05 ml. of a 1 mgm./ml. concentration) reduced, but did not abolish, the antithrombin activity of cerebrospinal fluid as compared with control reactions with distilled water (0.05 ml.). The antithrombin activity of normal cerebrospinal fluid did not change after adsorption on barium sulphate, but disappeared after addition of ether. Heating for 1 hr. at 45° C. did not influence essentially the antithrombin activity of normal cerebrospinal fluid. After 10 min. at 75° and 1 min. at 100° the antithrombin activity of normal cerebrospinal fluid disappeared.

* Determinations of October 14, 17, 19, and 24, 1960.
† Ventricular cerebrospinal fluid.

The second group of experiments concerned twelve specimens of fluid with abnormal results in the laboratory tests (Table 2). The inactivation of thrombin in pathological fluid is greater than in normal fluid and sometimes even greater than in serum. The results show no correlation between the protein-level or pleocytosis and antithrombin activity of the pathological cerebrospinal fluid. In one case of pneumococcal meningitis the antithrombin activity decreased in parallel to the improvement of clinical signs and laboratory tests. In a patient with hydrocephaly the cerebrospinal fluid obtained by ventricular puncture showed a lower antithrombin activity than the fluid obtained by lumbar puncture. The pathological antithrombin activity disappears after adsorption on barium sulphate and after 10 min. heating at 75° (Table 1).

Our results provide evidence for the existence of an antithrombin activity in normal and pathological cerebrospinal fluid. We have been able to determine some of their physico-chemical and biological properties which allowed us to differentiate between the normal and pathological antithrombins of cerebrospinal fluid and the blood antithrombins (Table 3).

The antithrombin of normal cerebrospinal fluid has a progressive action considerably weaker than that of the blood antithrombin or of pathological fluid. Toluidine blue and protamine sulphate reduce

Acidified virus (*p*H 5 0)	2 0	3 7	3 4
Same + 100 μgm ribonuclease per ml	1 8	1 7	—

by centrifuging the control and acidified virus suspensions at 30,000 r p m for 1 hr in the *L*40 head of the Spinco ultracentrifuge The upper and lower 5-ml fractions from each tube were then separated and titrated for virus content and also extracted with phenol and the infective ribonucleic acid estimated The results in Table 1 show that more than 90 per cent of the infective ribonucleic acid which could be extracted from the control virus was present, as virus, in the lower 5-ml fraction In contrast, equal amounts of infective ribonucleic acid could be extracted from the upper and lower 5-ml fractions of the acidified virus, indicating that the entity from which the infective ribonucleic acid was extracted had a smaller sedimentation constant than the initial virus Complement-fixation tests on the fractions showed that this activity also was distributed equally between the two fractions of the acidified virus, confirming the previous finding of Randrup[7] that the virus had disrupted to yield smaller complement-fixing particles Unacidified virus preparations contained only 20 per cent of the initial complement-fixing activity in the top 5 ml when centrifuged under the same conditions

Although these results showed that acidified virus suspensions contained a fragment which was smaller than the initial virus but which still yielded infective ribonucleic acid on extraction with phenol, they could not be taken as conclusive evidence that the infective ribonucleic acid itself had been released from the virus particle Some evidence has been obtained, however, which makes this seem likely By lowering the *p*H of the virus suspension in 0 1 per cent sodium dodecyl sulphate to 5 0, a product was obtained which was of low infectivity when tested intraperitoneally in mice (Table 2) This suspension was, however, about fifty times more infective when inoculated intracerebrally, but all this extra infectivity could be destroyed by adding 100 μgm ribonuclease per ml Moreover, the infectivity of the acidified virus tested intracerebrally was as high as that of the ribonucleic acid which could be obtained from it by phenol extraction It appears likely, therefore, that the infective material which was left after acidification was mainly the viral ribonucleic acid itself

Some of these experiments have been repeated with a foot-and-mouth disease virus of type *C* (strain 997) grown in tissue culture In these experiments also it was possible to extract infective ribonucleic acid from acidified virus of low virus infectivity These results thus confirm the earlier work of Mussgay[10] and also show that the dissociation of foot-and-mouth disease virus into its nucleic acid and protein components is not confined to one type of the virus

ANTITHROMBIN ACTIVITY OF NORMAL AND PATHOLOGICAL CEREBROSPINAL FLUID

By DR H A GAERTNER*, J LISIEWICZ and DR. J. CAEN

Blood Coagulation Laboratory, Third Medical Clinic, Krakow, and Institute for Research in Blood Diseases and Leukæmia, Claude-Bernard Association, Saint-Louis Hospital, Paris

THE coagulant activity of cerebrospinal fluid has been ascribed either to the presence of a thromboplastin[1-4] or of a factor-VIII-like[5] activity Some authors[2-4,6] admitted that cerebrospinal fluid may contain small amounts of prothrombin Normal cerebrospinal fluid contains neither fibrinogen nor fibrin, they appear in pathological cerebrospinal fluid when its protein-level increases beyond 100 mgm per cent[7]

Other investigators demonstrated the anticoagulant properties of cerebrospinal fluid In idiopathic hæmorrhage the red clot does not form from the extravasated blood in the presence of cerebrospinal fluid[8] The fibrinogen of tuberculous cerebrospinal fluid clots more slowly than the fibrinogen of the

Estimates of the volume of mixed saliva put out per day by anæsthetized and conscious sheep, and of the daily salivary nitrogen input to the reticulo-rumen of these animals are shown in Table 3 The estimate for total daily saliva output by conscious sheep agrees substantially with Somers's[7] estimate of 5 1 (range 3–6 1) Whereas Somers[7] has indicated a mean daily saliva nitrogen input to the reticulo-rumen of 0 7–0 9 gm for conscious sheep, I have found a lower value (mean 0 47 gm /day, range, 0 06–1 84 gm day), but I have obtained close agreement with Somers's estimate[7] for conscious sheep with his value of 0 75 gm /day for anæsthetized animals

The negative relationship between rate of saliva flow and saliva nitrogen previously discussed is apparent in these mean values for anæsthetized and conscious sheep This relationship suggests that despite considerable increase in the secretion of mixed saliva, such as during feeding, the total amount of saliva nitrogen entering the rumen with the ingested feed is not greatly increased

Thanks are due to Dr D F Stewart, associate chief of the Division of Animal Health, Commonwealth Scientific and Industrial Research Organization, McMaster Laboratory, Sydney, for making available animal house facilities Particular thanks are due to Mr H Lahoud, laboratory attendant, and Mr S A S Douglas of the School of Wool Technology for chemical analyses of some of these samples

DISSOCIATION OF FOOT-AND-MOUTH DISEASE VIRUS INTO ITS NUCLEIC ACID AND PROTEIN COMPONENTS

By F. BROWN and B. CARTWRIGHT

Research Institute (Animal Virus Diseases), Pirbright, Surrey

IT is well established that preparations of many different animal viruses contain smaller particles in association with the infective virus particle Included in this group are the viruses of influenza[1], rabies[2], poliomyelitis[3], Rift Valley fever[4]. African horse sickness[5] and foot-and-mouth disease[6] In the latter case it has also been shown that the larger 25-mμ infective particle can be dissociated into the 7-mμ particle by lowering the *p*H to about 6 (ref 7) or by heating at 56° C (refs 8 and 9) Recent work by Mussgay[10] showed that lowering the *p*H resulted in the release of the infective ribonucleic acid core of the virus, and Bachrach[11] has since demonstrated that a similar release of the infective ribonucleic acid occurs when the virus is heated at 56° C The latter author, however, was unable to confirm Mussgay's findings with acidified virus[12] The present experiments were carried out in an attempt to resolve the differences between the results of these workers, as their findings have an important bearing on the structure of the infective particle

The infective ribonucleic acid which can be extracted with phenol from foot-and-mouth disease virus is extremely sensitive to environmental ribonuclease[12,13] In experiments designed to show the presence of the infective ribonucleic acid, therefore, it is necessary for the enzyme to be removed from the viral suspensions or for its action to be completely inhibited In most of the experiments described here, vesicular fluid obtained from guinea pigs infected with strain 1 (immunological type *O*) was used as the source of virus This was partly freed from ribonuclease by three successive precipitations with half-saturated ammonium sulphate The precipitated virus was then re-suspended at 1/10 of its initial concentration in 0 1 per cent sodium dodecyl sulphate, which was a concentration sufficient to protect infective viral ribonucleic acid from the action of the ribonuclease remaining in the virus suspension Lowering the *p*H of this suspension to 5 6 led to a considerable reduction in virus titre (measured by intraperitoneal inoculation of 7-day-old mice) As much infective ribonucleic acid could be extracted with phenol from this acidified virus, however, as from the initial virus (Table 1) Infective ribonucleic acid was estimated by intracerebral inoculation of mice, as it is non-infective when administered intraperitoneally

Evidence that acidification had caused breakdown of the virus into smaller particles was obtained

Note On no occasion reported here were fistulæ blocked either by 'packing' of feed, or by the polythene collection bags pressing against them

docile than others Before sampling, the mouth and the œsophagus were washed out with distilled water At sampling, most, if not all, of the saliva passed via fistula from the conscious sheep and was collected The fluid in these cases was almost invariably ejected as a cohesive volume rather than as a steady trickle On the other hand, the experimental conditions of collection of saliva as it dripped from the gagged mouth of anæsthetized animals were almost constant. It is reasonable to conclude that collection of saliva from these sheep was complete The mean concentration of sodium and potassium in the mixed saliva of one conscious, fistulated sheep (seven half-hourly sub-samples) were 138 5 m equiv /l and 35 7 m equiv /l respectively The electrolyte composition of saliva from anæsthetized sheep was not examined

For all values reported, other than ash and *p*H, there is a wider variation for conscious than for anæsthetized animals Table 2 shows the mean values and their range These findings agree substantially with other estimates appearing in the literature

The large differences in rate of flow, total nitrogen and solids content between anæsthetized and conscious sheep are presumably due to the greater barrage of saliva eliciting stimuli received by the conscious sheep Since the ash contents were similar, it is suggested that most of the difference in total solids content obtained for these two treatments is due to a difference in organic matter content—presumably mucoproteins This is supported by the markedly higher (mean difference 13 2 mgm per cent) nitrogen content of saliva from anæsthetized than from conscious animals

A significant negative relationship obtained between flow-rate of mixed saliva and total nitrogen content for each of two anæsthetized sheep ($r = -0\ 72$, $P < 0\ 001$, 26 degrees of freedom, $r = -0\ 67$, $P < 0\ 001$, 20 degrees of freedom) There were insufficient observations per animal to permit any conclusions about the existence of a similar relationship for saliva from conscious animals

These results relate to the diversion of mixed saliva from anæsthetized sheep for time periods of up to 6 hr after consumption of a diet containing 11 per cent crude protein They support Phillipson and Mangan's[4] suggestion that the nitrogen content of saliva could be diluted by increasing rates of fluid secretion

On the other hand, Somers[5] found a positive relationship between rate of secretion and nitrogen content of mixed saliva ($r = 0\ 9212$, $P < 0\ 001$) His values are independent of time, mine depend on time Therefore the two analyses are not comparable In a later paper Somers[6], when examining a time-dependent relationship between total saliva nitrogen and parotid saliva volume secreted over a 24-hr period for conscious sheep following feeding, showed an apparent positive relationship between these values Diets of different nitrogen contents were used by Somers and by me This, together with the different saliva fluids examined, could explain the two sets of findings

Table 2 SHOWING COMPARISON BETWEEN CERTAIN SALIVA PROPERTIES FOR ANÆSTHETIZED AND CONSCIOUS SHEEP
(Mean values)

follows then that there would be two synapse-like sites in this linking mechanism: one is in the vicinity of the plasma membrane or between the plasma membrane and the endoplasmic reticulum, and the other between the reticulum and the contractile system. The 'glycerol effect' would be chemically (for this effect is highly specific to glycerol) or osmotically related to the former.

Details of this work are to be published elsewhere, with further experimental evidence.

We have found, in addition, a conspicuous effect. If, in these experiments, the normal Ringer's fluid is restored, the development of tension in the fibre by electrical stimulation is reduced and then abolished within a few minutes, in spite of the production of the vigorous action potential. We have no explanation at present of this effect.

We thank Prof. T. Nagai for his constant advice and Prof. E. Miyazaki for his encouragement. We are also grateful to Dr. T. Matsushima, Miss K. Abe and Mr. T. Yamamoto for assistance.

MIXED SALIVA FROM SHEEP

By W. R. McMANUS

School of Wool Technology, University of New South Wales, Sydney

IT is well known that the parotid glands of adult ruminants produce saliva continuously and their output volumetrically dominates the relatively smaller contribution made by the other salivary glands. Most reports agree that the submaxillary and sublingual glands chiefly function during the consumption of feed. The buccal glands have received little investigation. The saliva arising from the four types of glands is chemically different. There are few reports in the literature on the properties and flow-rates of mixed ovine saliva, especially on the quantity of endogenous nitrogen re-cycled to the rumen.

In many nutritional investigations on sheep there is need for information on the volume of saliva passing to the reticulo-rumen. Denton[1], using parotid fistulated sheep, has noted values for the flow of parotid saliva of animals consuming roughage and succulent rations. The observations of Bath *et al.*[2], conducted with one œsophageal fistulated sheep, have indicated the volume of mixed saliva put out while this animal consumed lucerne chaff—but the interval of time was not recorded.

The two experiments reported here were made during the course of a series of basic investigations on sheep fitted with chronic œsophageal fistulæ[3]. The fistulæ differed in area (2·0–8·0 cm.^{2}) and were all well healed.

Experiment 1 is concerned with minimal estimates of the volume of mixed saliva passing to the reticulo-rumen of sheep while consuming two types of roughage rations. Experiment 2 compares the composition and flow-rates of mixed saliva of anæsthetized sheep and conscious sheep while not consuming feed.

Table 1 shows the flow-rates of mixed saliva achieved on nine occasions in experiment 1 by five œsophageal fistulated sheep when consuming either a 55 per cent wheat grain, 25 per cent wheaten chaff and 20 per cent lucerne chaff ration (diet 1), or good quality lucerne chaff (diet 2) of known moisture contents. Information on duration of sampling, amount of ration consumed and the percentage recovery, via fistula, of extruded feed are also given.

Fistula extrusa was collected in polythene bags fitted around the animals' neck. Saliva flow-rates were estimated in the following manner. The 'free' saliva fluid was carefully separated from the particulate matter of the extrusa by compression and the fluid volume measured. The 'wet' particulate matter was weighed, oven-dried at 100° C. overnight and the moisture loss noted. After correction for the initial feed moisture content, the fluid volume difference between the 'wet' and 'dry' feed extrusa was added to the 'free' (saliva) fluid volume.

It is considered that this summated value represents the volume of saliva extruded from the fistulæ over the sampling period.

All attempts to occlude the œsophagus below the fistula, so as to ensure complete recovery of swallowed matter via fistulæ, resulted in distress to the animal. In experiment 1 an unknown amount of saliva by-passed the fistula and with the food entered the reticulo-rumen. Therefore these results do not represent estimates of the maximum volumes of saliva secreted by these sheep while consuming feed. However, they do reflect rates of mixed saliva secretion that can be achieved, and exceeded, by sheep while eating these roughage rations (mean 8·5 ml./min., range, 3·8–12·0 ml./min.). In contrast, the mean saliva flow-rate for conscious œsophageal fistulated sheep (not eating, experiment 2) was only half as great (4·3 ml./min., range, 0·52–17·0 ml./min.).

For experiment 2, six œsophageal fistulated and three non-fistulated animals were used. Twenty-one observations were made on the diversion and collection of mixed saliva from either conscious fistulated sheep (without concomitant consumption of feed), or orally from anæsthetized non-fistulated sheep ('Kemithal', lateral recumbency). For conscious sheep the collection periods ranged from 6 to 335 min. (mean 71·7 min.), and for the anæsthetized sheep from 268 to 370 min. (mean 300·2 min.).

The experimental conditions for the fistulated sheep varied widely between occasions. Some animals were fasted for 12 hr. before sampling, others were fed immediately before sampling. In some cases food was within the animals' sight—but in no case was the animal consuming its ration when saliva samples were collected. Some animals were more

(1) The time of re-appearance of the twitch and the gradation of the twitches are intimately related to the duration for which the muscle is immersed in Ringer's fluid containing glycerol, and are not affected by the intervals (1–9 min.) at which a stimulation to evoke twitch is given. (2) This phenomenon is recognizable over the wide range of glycerol concentrations (120–840 m*M*), though it becomes obscure at both extremes of concentration—at the higher concentrations, due to the reduced contraction of the re-appeared twitch; at the lower one, due to the small diminution of the mechanical response. (3) Under various hypertonic conditions, produced by adding sodium chloride (150–250 m*M*) or several non-electrolytes (mannitol, 50–400 m*M*; monoacetin $CH_2OH{\cdot}CHOH{\cdot}CH_2OCOCH_3$, 50–300 m*M*; glucose, 200–400 m*M*; sucrose, 200–300 m*M*, and urea, 300 m*M*) to normal Ringer's fluid, only diminution or abolition of twitch occurs; hence the re-appearance of twitch after diminution is highly specific to glycerol, and the term the 'glycerol effect' is quite justified. (4) The 'glycerol effect' appears also in the case of sartorius muscle (13 m*M* potassium chloride) depolarized with potassium, when stimulated in either a longitudinal or a transverse a.c. (50 c./s.) electric field (8–10 V./cm., 40–94 msec.). Another series of experiments showed that the 'glycerol effect' occurs in whole muscle of the frog rectus abdominis, whereas it does not in the frog heart ventricle. We have found that the 'glycerol effect' is recognizable in Ringer's fluid without calcium or potassium or both.

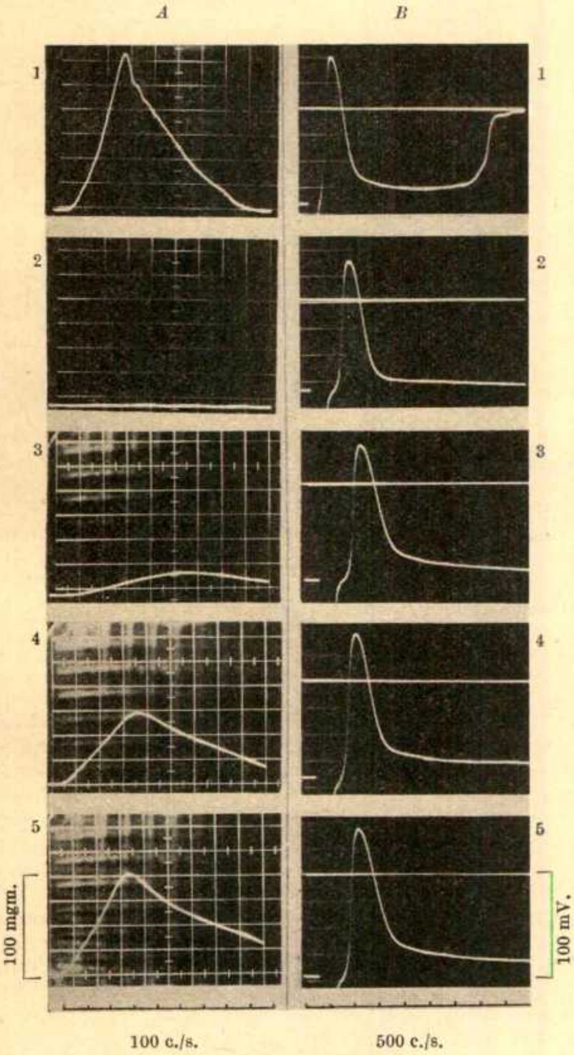

Fig. 1. Mechanical and electrical responses of single muscle fibres of the frog semitendinosus at different times after replacing the Ringer's fluid by the one containing 420 m*M* glycerol

The series of records *A* shows twitch tensions obtained from a single muscle fibre: *A*1, in normal Ringer's fluid; *A*2, *A*3, *A*4 and *A*5, after soaking in glycerol Ringer's fluid for 1 min., 24 min., 44 min. and 60 min., respectively. The series of records *B* shows action potentials obtained from single muscle fibres of a bundle: *B*1, in normal Ringer's fluid (dislodging the micro-electrode caused by the movement of the fibre resulted in the displacement of the tracing to 0 mV. at the right-hand side); *B*2, *B*3, *B*4 and *B*5, after soaking in glycerol Ringer's fluid for 3 min., 26 min., 45 min. and 60 min., respectively

The fibres were stimulated by means of a pair of external electrodes with a square pulse generated from an electronic stimulator at room temperature (17° C.). The tension recorder was a mechano-electronic transducer *RCA* 5734, and glass capillary micro-electrodes filled with 3 *M* potassium chloride (10–30 megohms) were employed to record action potentials. The Ringer's fluid contained 122 m*M* sodium chloride, 2 m*M* potassium biphosphate, 1·3 m*M* calcium chloride and was buffered to *p*H 7·0 with sodium bicarbonate

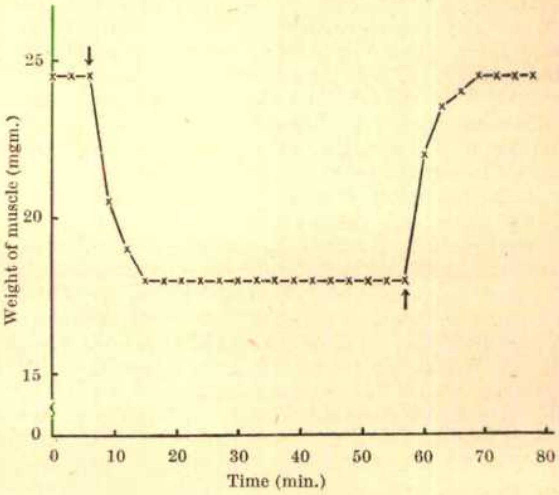

Fig. 2. Osmotic effect of hypertonic Ringer's fluid containing 420 m*M* glycerol on whole muscle of frog sartorius

At ↓, the bathing fluid was exchanged with the glycerol Ringer's fluid, and at ↑, the normal Ringer's fluid was restored. The muscle was weighed on a torsion balance after it was blotted carefully with pieces of filter paper

From these results it is clear that the re-appearance of the mechanical activity takes place as the result of the effect of glycerol on a significant process (or processes) which links the membrane excitation with the contraction and is paralysed under the hypertonic condition. Since glycerol is not considered to diffuse into a muscle fibre, at least within the 10–20 min. in which the 'glycerol effect' begins to appear (no further detectable change in muscle weight occurs at this time (Fig. 2); Bozler, E., personal communication), it is believed that this process exists at the plasma membrane or at its vicinity. It follows also that the contraction both in the transverse a.c. field and in the longitudinal field would not be due to any internal currents flowing within a muscle fibre, but to activation of a process at the membrane or in its vicinity[7,8].

How this 'glycerol effect' occurs is at present difficult to understand. The following explanation is very speculative: we have already pointed out the possibility of the existence of a synapse-like process in the sequence of processes linking excitation with contraction[9]. On the other hand, it is probable, according to Huxley[10], that the *Z*-line or the endoplasmic reticulum is the structure responsible for the electrical spread of excitation in question. It

The presence of pyridoxal and pyridoxal phosphate in the vicinity of isolated Ehrlich ascites tumour cells intensifies their uptake of amino-acids, both under aerobic[9] and anaerobic[10] conditions. These tumour cells quickly take up pyridoxal to an extent calculated to be 1·3–1·4 times that of the extra-cellular level of the vitamin[11]. This is understandable, since Ehrlich ascites tumour cells have been reported to have a greater capacity to take up amino-acids from the blood and concentrate them, than have normal cells[12]. These findings are also compatible with the known primary functions of vitamin B_6 as a coenzyme in amino-acid decarboxylation, transamination and catalytic breakdown of tryptophan. Our observations of the reversing effect by pyridoxine and pyridoxamine on 5-FU and 5-FUDR growth inhibition of *C. albicans* directs attention to the possibility of a new function of vitamin B_6 in nucleic acid metabolism, as well as a possible new mode of action of the 5-fluoropyrimidines. The antagonism between vitamin B_6 and 5-fluoropyrimidines also raises the question as to whether 5-fluoropyrimidine-resistant cancer cells possess a 'built-in' resistance mechanism by virtue of possessing greater levels of B_6 or by their synthesizing greater quantities of the vitamin than do susceptible cancer cells. The effect of vitamin B_6 on 5-fluoro-pyrimidine-intoxicated animals, with and without transplanted tumours, in order to determine the ability of vitamin B_6 to reduce parenteral toxicity of the 5-fluoropyrimidines, is the next area of exploration under consideration. Investigations along some of these lines are under way.

This investigation was supported by a research grant, *G*-7072, of the National Science Foundation, Washington, D.C.

'GLYCEROL EFFECT' AND THE MECHANISM LINKING EXCITATION OF THE PLASMA MEMBRANE WITH CONTRACTION

By Prof. MASAHIRO FUJINO, TOSHIO YAMAGUCHI and KEISHI SUZUKI

Department of Physiology, Sapporo Medical College, Sapporo, Japan

FOR various reasons, it seemed of interest to consider the use of glycerol and/or other non-electrolyte in investigating the mechanism of a 'membrane'. Thus: (1) in the biochemical and biophysical fields[1,2], glycerol has been used for disintegrating the cell membrane, suggesting the possibility that it might have an effect on other membrane systems of the muscle cell, for example, sarcoplasmic reticulum[3]; (2) glycerol is a constituent member of the lipid part of lipoprotein, which seems to form the framework of the membrane system of the cell[4]. We have therefore investigated the relationship between glycerol and the activity of muscle, in an attempt to elucidate the mechanism of the excitation-contraction link of the muscle cell, using the 'glycerol effect' for this purpose.

If a single muscle fibre from the frog's skeletal muscle (m. tibiofibularis and m. semitendinosus of *Rana nigromaculata* or *Rana japonica*) is immersed in a Ringer's fluid which is hypertonic due to the addition of a high concentration of glycerol, say, about 420 m*M*, the mechanical response in twitch declines and then disappears within about 1 min. (Fig. 1*A*2). Nevertheless, such fibres are electrically excitable, and the action and resting potentials are almost unchanged (Fig. 1*B*2), though the rate of rise and fall of the action potential is likely to be slightly reduced. Since the diminution of the mechanical response due to the hypertonic condition and the differential action on the mechanical response and action potential of a muscle fibre have been already reported[5,6], this effect as such is not new. The disappearance of the mechanical response is considered to be due not to the chemical effect of glycerol but to the hypertonicity of the Ringer's fluid used; this view is supported by the fact that the disappearance of the response is accompanied by a considerable loss of weight of muscle (Fig. 2).

About 6–10 min. after immersion in Ringer's fluid containing glycerol, however, a new observation, which we have called the 'glycerol effect', appears. As shown in Fig. 1*A*, in spite of being left in the hypertonic condition, mechanical response in the form of twitch re-appears, the twitch tension rises gradually and reaches 50–70 per cent (maximum value) of the normal within 40–60 min. after re-appearance. It is very interesting that the restoration takes place without any further changes in either action or resting potential (Fig. 1*B*) and even in the weight of muscle (Fig. 2).

These results indicate directly that the disappearance of the ability to develop twitch tension under hypertonic conditions occurs not by alteration of the contractile system due to dehydration, but by paralysis of function of a strategic system linking the excitation of the plasma membrane with the contraction.

A similar phenomenon, namely, the disappearance of the mechanical response followed by its re-appearance is also recognizable in the case of complete tetanus, which is evoked at appropriate intervals to test the contractibility.

Experiments with the isotonic lever on whole muscle of the frog sartorius give the following results:

order of addition of metabolite and antimetabolite was not crucial, both vitamin B_6 and 5-fluoropyrimidines were introduced together with the inoculum. As seen in Tables 1 and 2, inhibition indices for both 5-FU and 5-FUDR for *C. albicans* were small, indicating very high antimetabolite activity of the 5-fluoropyrimidines in the *C. albicans* test system. However, the inhibition indices were not constant for either pyridoxine or pyridoxamine versus 5-FU or 5-FUDR and the antagonism was non-competitive. This would indicate that vitamin B_6 competes with the 5-fluoropyrimidines at more than one site on the cell.

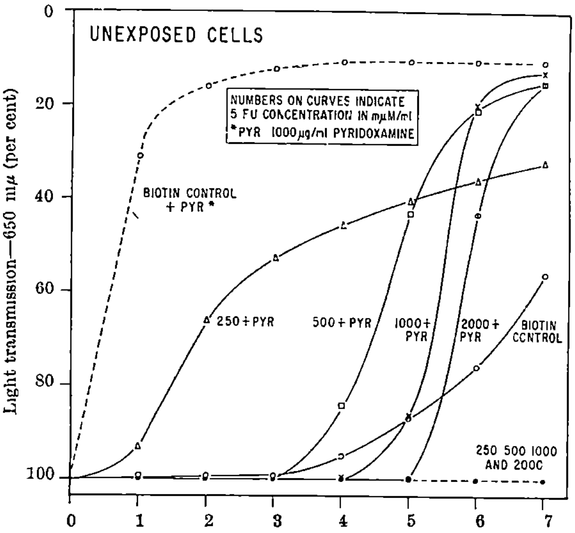

Fig. 4. The reversing action of pyridoxamine (1,000 μgm./ml.) on growth inhibitory effect of 5-FU on previously unexposed cells of *C. albicans* at four levels of 5-FU at 28° C. in basal synthetic culture medium in incubator shaker at 250 cyles/min. Metabolite and antimetabolite introduced together. Biotin control tubes, with and without pyridoxamine, do not contain 5-FU. Note complete inhibition without escape, by 250, 500, 1,000 and 2,000 mμmoles 5-FU/ml., in absence of pyridoxamine. Each point represents an average of triplicate values, arithmetic plot

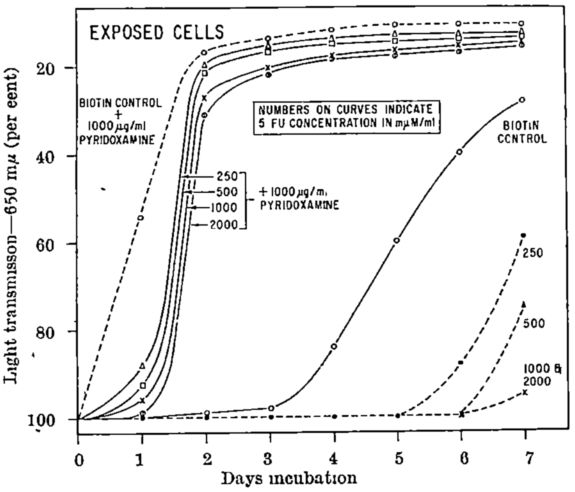

Fig. 5. The reversing action of pyridoxamine (1,000 μgm./ml.) on growth inhibition of 5-FU on cells of *C. albicans* previously in continuous contact for seven days with an 80 per cent inhibitory dose of 5-FU (0·30 μmole/ml.). Test run at four levels of 5-FU at 28° C. in basal synthetic culture medium in incubator shaker at 250 cycles/min. Metabolite and antimetabolite introduced together. Biotin control tubes, with and without pyridoxamine, do not contain 5-FU. Note complete inhibition with escape in tubes containing 250, 500, 1,000 and 2,000 mμmoles 5-FU/ml., in absence of pyridoxamine. Each point represents an average of triplicate values, arithmetic plot

Table 1. AMOUNTS OF 5-FU REQUIRED TO PRODUCE HALF-MAXIMAL INHIBITION OF GROWTH OF *Candida albicans* IN THE PRESENCE OF VARYING AMOUNTS OF PYRIDOXAMINE AND PYRIDOXINE

* Inhibition index = (ID_{50} of 5-FUDR in presence of metabolite) minus (ID_{50} in absence of metabolite) divided by (concentration of metabolite)

The 5-fluoropyrimidines inhibit mammalian tumours by interfering with synthesis of ribonucleic (RNA) and deoxyribonucleic (DNA) acids[4-6]. They inhibit incorporation of formate, uracil-4-carboxylic acid and pyrimidines into DNA thymine of liver, spleen and the Ehrlich tumour *in vivo*. They also block the incorporation of uracil and uracil-4-carboxylic acid into RNA uracil. The most important site of action is in the inhibition of methylation of uridylic acid to form thymidylic acid[5]. Analogous effects of thymine and uracil metabolism have been shown to occur in microbiological systems, such as *Escherichia coli*[7], *Staphylococcus aureus*[8], and others. It is reasonable, therefore, to postulate that at least one of the inhibitory effects of 5-FU and 5-FUDR on *C. albicans* is due to interference with nucleoprotein synthesis in this organism. Further work, however, will be required to confirm this hypothesis.

In view of the fact that the growth-restricting action of 5-FU and 5-FUDR on *C. albicans* was reversed by vitamin B_6, and that growth of the organism continued to be restricted by increasing concentrations of 5-fluoropyrimidines despite the presence of optimal concentrations of vitamin B_6, we can assume that the 5-fluoropyrimidines interfere in some manner with uptake or utilization of vitamin B_6 by the yeast cell, unless the vitamin was itself involved in nucleoprotein synthesis. We are not aware of any reports that vitamin B_6 is thus involved. We did observe that when exhausted cells of *C. albicans*, both exposed and unexposed to the prior inhibitory effects of 5-FU, were given pyridoxamine, the unduly prolonged lag phase of the organism promptly disappeared (Figs. 4 and 5), indicating a salutary effect on cellular reproduction.

10 mμmoles 5-FUDR/ml or higher with at least 5,000 mμmoles pyridoxamine/ml

Partial purification of the pigment produced by *C albicans* from 5-FU and pyridoxamine was accomplished by de-ionization of filtered supernatant fluid with '*IRC*-50' cationic exchanger, adsorption at pH 3 with 'Darco *G*60' activated charcoal, followed by several washings with distilled water, after which the pigment was eluted from the charcoal with alkaline 50 per cent ethanol, to yield a clear yellow solution The pigmented product behaved as an indicator in this solution

pH	Colour
< 1	No colour
2	Light reddish violet
2 8–3 5	Red
5 5–6 5	Yellowish pink
6 5–11	Yellowish brown
> 12	Yellow

The yellow solution was adjusted with hydrochloric acid to a red colour at pH 3 In ascending paper chromatograms in n-butanol/methanol/benzene/water = 2 1 1 1 (upper layer) for 15 hr at 22° C, the red-coloured product, not fluorescent in ultra-violet light, migrated to R_F 0 43, interspersed, but clearly separable, from five other fluorescent unpigmented spots When tested against *C albicans*, the pigmented, metabolic product was neither growth-inhibitory nor growth-stimulatory in seeded basal synthetic culture medium agar Further purification and characterization of this pigment is proceeding

Order of introduction of metabolite versus antimetabolite in test system Further experiments were conducted to determine whether the order of addition of the metabolite and antimetabolite was crucial for the reversal action of the metabolite Pyridoxine and pyridoxamine were introduced simultaneously, first with 5-FU and then with 5-FUDR, into basal synthetic culture medium, followed immediately by addition of the standard inoculum of vitamin-depleted yeast cells Under these new conditions, pyridoxamine (Fig 3) and pyridoxine were again capable of reversing the toxicity of 5-FU for *C albicans* Substitution of 5-FUDR produced similar results except that pyridoxamine was more effective in reversing 5-FUDR inhibition than was pyridoxine The order of addition of vitamin B_6 and the 5-fluoropyrimidines is therefore not crucial Vitamin B_6 reversed the toxicity of 5-FU for cells in prior contact with 5-FU for 4 days (Fig 2), as well as for cells previously unexposed to 5-FU (Fig 3)

Reversal of 5-FU inhibition by vitamin B_6 using 5-FU exposed and unexposed cells Inocula in the preceding experiments had consisted of vitamin-depleted yeast cells previously unexposed to 5-fluoropyrimidines or to vitamin B_6 We now wished to determine whether yeast cells continually exposed to 60 μgm 5-FU/ml for a 7-day period at 28° C would respond to the reversing action of vitamin B_6 in the same manner as unexposed cells Accordingly, yeast cells that had been incubated 7 days in the shaker in the presence and absence of 5-FU were collected, washed three times with sterile, double-distilled water, re-suspended, and adjusted to 50 per cent light transmission These 7-day-old cells were re-inoculated into fresh tubes of basal synthetic culture medium containing 5-FU, with and without 1,000 μgm pyridoxamine/ml As seen in Figs 4 and 5, a 7-day prior period of incubation, whether in the presence of 60 μgm 5-FU/ml or not, was capable of exhausting the reproductive ability of *C albicans* and prolonging the lag phase of growth to 3 days (biotin control curves) However, when pyridoxamine was added with biotin, the prolonged lag phase was eliminated regardless of whether the cells had been exposed to 5-FU or not (biotin + pyridoxamine curve) This action of pyridoxamine points to it as having an important role in the cellular reproduction of *C albicans*

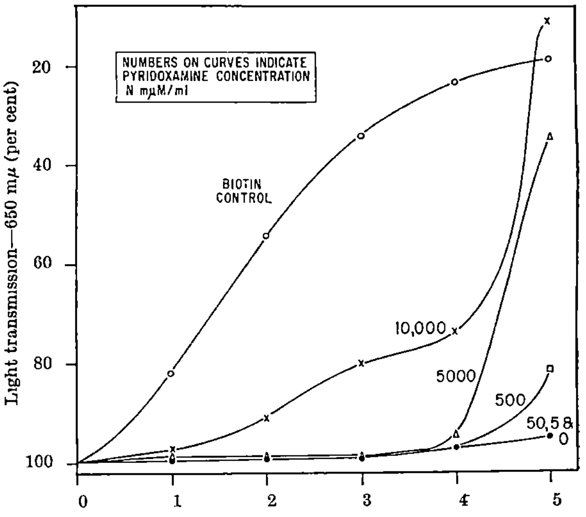

Fig 3 Growth response of *C albicans* and the reversing effect of five levels of pyridoxamine on growth inhibition by 5-FU at 28° C in incubator shaker in basal synthetic culture medium at 250 cycles/min All tubes contain 1,000 mμmoles 5-FU/ml except biotin control Metabolite and antimetabolite introduced together Each point represents an average of triplicate values, arithmetic plot

5-FU exposed yeast cells were completely inhibited by second contact with 5-FU over the range 250–2,000 mμmoles/ml within the 5-day incubation period (Fig 5) However, appreciable escape from inhibition by 5-FU began to occur by the sixth and seventh day, signalling what we interpret as the emergence of 5-FU adapted or resistant cells In the case of unexposed cells, there was also complete inhibition by 5-FU over the same range of concentration, but no escape occurred over a 7-day incubation period (Fig 4) Thus, prior conditioning to 5-FU appears to favour the emergence of 5-FU adapted or resistant cells The future usefulness of 5-FU resistant *C albicans* cells as an indicator system for screening useful compounds for 5-FU-resistant cancer lines, remains to be determined In comparing the speed of reversal by pyridoxamine of growth inhibition of 5-FU exposed yeast cells and unexposed cells, one notes more rapid reversal of growth inhibition of exposed cells than that of unexposed cells (Figs 4 and 5) This may be attributed to (1) the adaptation or increased resistance to 5-FU of the yeast cell exposed twice to 5-FU, (2) to the accumulation of unused growth-stimulatory intermediate metabolites blocked by the prior contact with 5-FU

Type of antagonism between vitamin B_6 and 5-fluoropyrimidines In order to determine whether the antagonism between vitamin B_6 and the 5-fluoropyrimidines was competitive or non-competitive, a determination was made of the amounts of 5-FU and 5-FUDR which were required to cause half-maximal inhibition of growth in the presence of ascending ten-fold concentrations of pyridoxine and pyridoxamine (Tables 1 and 2) Since the water, after which the medium was adjusted to neutrality with 1 *N* sodium hydroxide The basal medium was distributed in 9-ml volumes to optically matched, chemically clean 'Lumetron' glass tubes which were covered with aluminium caps and sterilized by autoclaving at 118° C (12 lb) for 12 min Glass filter-sterilized solutions of varying concentrations of 5-FU, 5-FUDR and vitamin B_6, each contained in a volume of 1 ml , were then added aseptically After being seeded, tubes were incubated at 28° C in a New Brunswick Gyrotory Shaker under constant rotation at 250 cycles per min Daily turbidity measurements were made photometrically with a 401*A* 'Lumetron' colorimeter at 650 mμ The standard inoculum consisted of vitamin-depleted yeast cells prepared by subculturing the organism twice on vitamin-free basal synthetic culture medium agar slopes, with an intervening 7-day incubation period at 37° C By the time of the second sub-culture, growth of the organism had become sparse Vitamin-free washed agar incorporated in the formula was prepared by a previously described method[2] Vitamin-depleted yeast cell suspensions were collected and washed three times in sterile, double-distilled water, adjusted to 50 per cent light transmission at 650 mμ and then inoculated at a standard dose of 0 15 ml suspension per tube

Inhibitory effect of 5-*FU and* 5-*FUDR* Ascending concentrations of 5-fluoropyrimidines caused a progressive restriction of growth of *C albicans* to the point of complete inhibition in the case of 5-FU (Fig 1) and 60–70 per cent inhibition by 5-FUDR This inhibitory effect was observable within the first day of incubation and persisted for the entire 5-day observation period Some escape from the inhibitory effect of 60–90 μgm 5-FU/ml appeared by the fourth day of incubation (Fig 1) However, no escape from inhibition occurred from the effects of 5-FUDR over the same observation period 50 per cent minimal inhibiting dose (ID_{50}) of 5-FU varied from 31 to 37 μgm /ml (0 24–0 28 μmole/ml) from the second to fifth day of incubation, and averaged 34 3 μgm /ml (0 26 μmole/ml) The inhibitory action of 5-FUDR on *C albicans* was approximately ten times that of 5-FU, although, unlike the latter compound, it never produced complete restriction of growth at any concentration The ID_{50} of 5-FUDR varied from 3 9 to 1 86 μgm /ml (0 03–0 014 μmole/ml) from the second to fifth day of incubation, and averaged 2 9 μgm /ml (0 022 μmole/ml)

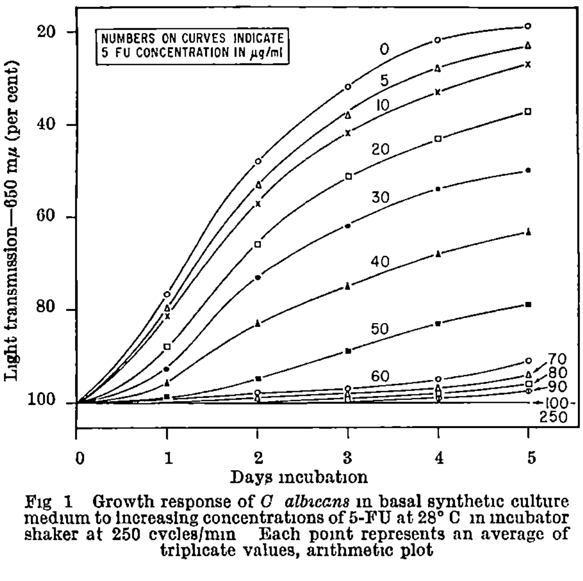

Fig 1 Growth response of *C albicans* in basal synthetic culture medium to increasing concentrations of 5-FU at 28° C in incubator shaker at 250 cycles/min Each point represents an average of triplicate values, arithmetic plot

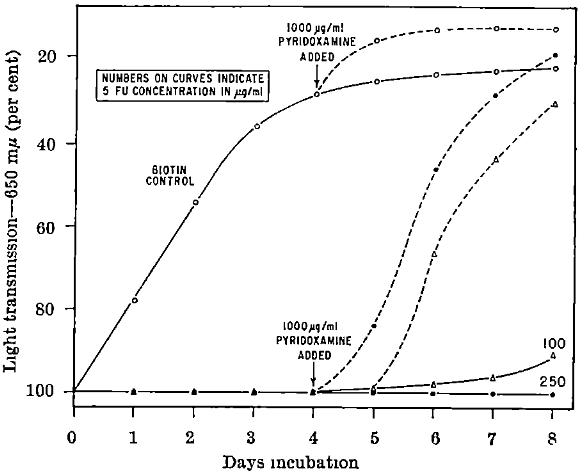

Fig 2 Reversing effect of pyridoxamine (1,000 μgm /ml) on growth-inhibition of cells of *C albicans* previously exposed for four days to high concentrations of 5-FU in basal synthetic culture medium at 28° C in incubator shaker at 250 cycles/min Each point represents an average of triplicate values, arithmetic plot

Reversing effect of pyridoxine and pyridoxamine Stimulated by the newly observed fact that five representative strains of *C albicans* had all shown a partial deficiency for pyridoxamine at an optimal concentration of 1,000 μgm /ml (ref 3), which is beyond the usual concentration for vitamins, we considered the possibility that vitamin B_6 could be involved in cell metabolism of *C albicans* other than as a coenzyme in amino-acid metabolism We therefore applied these vitamins to viable but growth-inhibited yeast suspensions containing ascending concentrations of both 5-FU and 5-FUDR We then observed that the growth-inhibiting effects of the two 5-fluoropyrimidines were reversed by pyridoxine as well as pyridoxamine To our knowledge, this phenomenon has not been reported previously As shown in Fig 2, the addition of 1,000 μgm pyridoxamine/ml (4 1 μmoles/ml) to incubating yeast cells on the fourth day of their continuous exposure to varying concentrations of 5-FU brought about a prompt reversal of growth inhibition The more pronounced reversals occurred at the higher concentrations of 5-FU (50–250 μgm /ml) than lower concentrations Reversal of 5-FU inhibition by pyridoxamine was complete in that final turbidities in pyridoxamine-reversed tubes were approximately equal to, or exceeded, those of biotin control tubes not containing 5-FU (Fig 2)

Extracellular pigment formation A water-soluble, extracellular, pigmented metabolic product of *C albicans*, which is ordinarily not a pigmented yeast, appeared regularly in all seeded tubes of basal synthetic culture medium containing 0 25 μmole 5-FU/ml or higher, whenever the concentration of pyridoxamine exceeded 5 μmoles/ml The coloured product diffused into the supernatant fluid after 24 hr of incubation and progressively increased in concentration with time Pigment was not produced when pyridoxine was substituted for pyridoxamine nor when 5-FU and pyridoxamine were shaken together in distilled water Substitution of 5-FUDR for 5-FU yielded a similar pigment with pyridoxamine, but not with pyridoxine This also occurred after the first day of incubation in tubes containing

The lack of effect of malonate on α-ketoglutarate-stimulated isocitrate oxidation is in favour of the second possibility, since acetoacetate formed by reaction (15) could readily be converted to acetoacetyl-coenzyme A by reaction (13)

Thus, it is possible to explain the stimulations by all the substrates listed in Table 1 in terms of their ability to promote the formation of acetoacetyl-coenzyme A (or other keto-acyl-coenzyme A intermediates of fatty acid synthesis and breakdown) An initial lag was found both in the incorporation of acetate into fatty acid promoted by citrate[1] and in the acetate-promoted oxidation of isocitrate (for example, 0 42 µmole in the first 15 min , 1 25 µmoles in the second and 0 76 µmole in the third) This is to be expected if a catalyst for the oxidation of citrate such as acetoacetyl-coenzyme A has to be formed after the mixing of the components of the reaction mixture

Chappell and Greville[23] have recently reported that the oxidation of isocitrate by rat-liver mitochondria is inhibited by the addition of lewisite or by the removal of phosphate in the presence of dinitrophenol (see also ref 24), procedures known to inhibit the oxidation of α-ketoglutarate They conclude that oxaloacetate formed by the further oxidation of the α-ketoglutarate is necessary for the oxidation of the mitochondrial TPNH This suggestion was supported by their finding that, in the presence of lewisite, catalytic amounts of malate promoted the oxidation of isocitrate

It is possible that the system in rat-liver mitochondria is different from that in rabbit-heart sarcosomes The reaction conditions used in this study were also different from those used by Chappell and Greville In any event, it seems unlikely that oxaloacetate is functioning directly to oxidize mitochondrial TPNH in my experiments for the following reasons (i) acetate decreases the concentration of oxaloacetate, as made evident by the stimulation by acetate of the oxidation of succinate, which is inhibited by oxaloacetate, and by the inhibition by acetate of the oxidation of glutamate which requires oxaloacetate[25], (ii) dinitrophenol which inhibits the oxidation of isocitrate causes increased concentrations of oxaloacetate[25], (iii) glutamate which removes oxaloacetate by transamination also promotes the oxidation of isocitrate, (iv) malonate does not inhibit the α-ketoglutarate-promoted oxidation of isocitrate

I wish to thank Prof E C Slater for his suggestions and criticism and Miss H M Moerdijk for technical assistance

REVERSAL OF TOXICITY OF 5-FLUOROURACIL AND 5-FLUORODEOXYURIDINE FOR *CANDIDA ALBICANS* BY PYRIDOXINE AND PYRIDOXAMINE

By Dr M L. LITTMAN and Dr T MIWATANI

Department of Microbiology, Mount Sinai Hospital, New York, and Osaka University Medical School, Osaka, Japan

DURING work on the metabolism of the pathogenic yeast, *Candida albicans*, we observed that the growth of this organism in a synthetic glucose mineral salt medium was markedly inhibited by the anti-cancer fluorinated uracil derivatives, 5-fluorouracil (5-FU, mol wt 130) and 5-fluorodeoxyuridine (5-FUDR, mol wt 246 2) (These compounds were kindly supplied by Hoffmann–La Roche, Inc , Nutley, New Jersey) In following the inhibitory action of these compounds, we noted also that such effects could be promptly reversed by the addition of pyridoxine and pyridoxamine In view of the high toxicity of the 5-fluoropyrimidines and the absence of clinically effective reversing compounds other than thymidine for 5-FUDR (ref 1), application of this observation *in vivo* in human and animal cancer therapy seems to be indicated

The basal synthetic culture medium, in which growth, growth-inhibition and inhibition-reversal occurred, contained the following ingredients glucose, 10 gm , ammonium sulphate, 2 gm , potassium dihydrogen phosphate, 2 gm , crystalline magnesium chloride, 0 2 gm , crystalline calcium chloride, 0·02 gm , crystalline -ferrous chloride, 0 04 gm , crystalline manganous chloride, 0 0015 gm , crystalline sodium molybdate, 0·0015 gm , and biotin, 1,000 mµgm , all dissolved in 900 ml potassium permanganate-oxidized double distilled

Sucrose, 50 mM, potassium chloride, 9.5 mM, ethylenediaminetetraacetate, 1 mM, potassium phosphate buffer (pH 7.5), 50 mM, magnesium chloride, 5 mM, triphosphopyridine nucleotide (TPN$^+$), 0.2 mM, adenosine triphosphate (ATP), 10mM, Ls(+)-isocitrate, 5 mM, coenzyme A, 0.18 mM, glutathione, 1.8 mM, rabbit-heart sarcosomes (isolated in sucrose-ATP, ref. 26), 1.72 mgm. protein in exp. 1, 1.62 mgm. in exp. 2, 1.72 mgm. in exp. 3 and 1.20 mgm. in exp. 4. Other additions, where shown: acetate, 3 mM, DL-β-hydroxybutyrate, 1 mM in exp. 1, 3 mM in exp. 2, 12 mM in exps. 3 and 4, α-ketoglutarate, 30 mM, succinate, 40 mM, L-malate, 30 mM, L-glutamate, 30 mM, 2,4-dinitrophenol, 0.1 mM, antimycin, 1 µgm./ml., malonate, 10–12 mM. 2 per cent ethanol was also present in all flasks of exps. 1 and 2. The reaction was carried out in a shaking manometer flask with 10 per cent potassium hydroxide and a filter paper in the centre well. The reaction was stopped after 40 min. (exp. 1), 45 min. (exp. 2), 60 min. (exps. 3 and 4), at 25° by adding trichloroacetic acid (final conc. 5 per cent). Isocitrate + citrate + aconitate were determined on the neutralized supernatant by measuring the reduction of TPN$^+$ in the presence of isocitrate dehydrogenase and aconitase. The values given for exps. 3 and 4 are the means of two experiments.

promote the rate-limiting reaction (4). It remains to be explained how acetate and the other compounds listed in Table 1 also promote the oxidation of intramitochondrial reduced triphosphopyridine nucleotide (TPNH). It is natural to link this process with the mechanism of fatty acid synthesis, which is known to involve the oxidation of TPNH (refs. 9–11). For example, it seems possible that acetoacetyl-coenzyme A could bring about the transhydrogenase reaction (4) by reactions (6) and (7):

TPNH + acetoacetyl-coenzyme A + H^+ →
TPN$^+$ + β-hydroxybutyryl-coenzyme A (6)

β-Hydroxybutyryl-coenzyme A + DPN$^+$ →
acetoacetyl-coenzyme A + DPNH + H^+ (7)

the sum of which is reaction (4). Experiments to be reported elsewhere have shown the presence of an enzyme catalysing the oxidation of TPNH by acetoacetyl-coenzyme A in digitonin extracts of rabbit-heart sarcosomes. Whether the product of reaction (6) has the L-configuration, which is the substrate for reaction (7) (ref. 12), is of minor importance, since mechanisms for converting the L-form to the D-form are known[13,14].

Acetate can yield acetoacetyl-coenzyme A by reactions (8) + (9) (refs. 15 and 16) or (8) + (10):

Acetate + coenzyme A + ATP →
acetyl-coenzyme A + AMP + pyrophosphate (8)

Acetyl-coenzyme A + malonyl-coenzyme A →
acetoacetyl-coenzyme A + coenzyme A + CO_2 (9)

2 acetyl-coenzyme A ⇌
acetoacetyl-coenzyme A + coenzyme A (10)

The malonyl-coenzyme A could be derived by reaction (2) from the oxalosuccinate formed by oxidation of isocitrate.

β-Hydroxybutyrate can be converted to acetoacetyl-coenzyme A by reactions (11) (ref. 12) and (12):

β-Hydroxybutyrate + coenzyme A + ATP ⇌
β-hydroxybutyryl-coenzyme A + AMP +
pyrophosphate (11)

β-Hydroxybutyryl-coenzyme A + $\frac{1}{2}O_2$ →
acetoacetyl-coenzyme A + H_2O (12)

Table 1 shows that the oxidation of isocitrate with added acetate or β-hydroxybutyrate is inhibited by dinitrophenol as would be expected according to these equations. The slow oxidation in the absence of acetate, which might be due to endogenous fatty acid, is also inhibited by dinitrophenol.

The stimulation of disappearance of isocitrate by succinate or malate in the absence of added acetate could be explained similarly, since these compounds give rise to acetyl-coenzyme A by oxidation of the pyruvate formed by decarboxylation of the oxaloacetate, and to malonyl-coenzyme A by reaction (1). Thus acetoacetyl-coenzyme A can be formed by reaction (9). The contribution of reaction (10) to the formation of acetoacetyl-coenzyme A in the absence of added acetate is likely to be small, because the equilibrium of this reaction is far to the left[15].

The stimulation of isocitrate oxidation by α-ketoglutarate cannot be explained on the same basis since it is not inhibited by malonate. It seems most likely that succinyl-coenzyme A formed by the oxidation of α-ketoglutarate is involved, but how is not certain. It is possible that acetoacetyl-coenzyme A is formed from traces of acetoacetate in the preparation by reaction (13) (refs. 17 and 18):

Succinyl-coenzyme A + acetoacetate ⇌
succinate + acetoacetyl-coenzyme A (13)

although no acetoacetate could be detected in the sarcosomal preparations by Walker's method[19]. The partial sensitivity to dinitrophenol of the stimulation of citrate oxidation by α-ketoglutarate might be due to the appreciable activity of the succinyl-coenzyme A deacylase in the presence of dinitrophenol and absence of fluoride[20]. Glutamate would be expected to act in the same way as α-ketoglutarate, since the oxidation of α-ketoglutarate to succinate is a compulsory step in the oxidation of this substrate by heart sarcosomes[21].

Two explanations for the effect of malonate might be considered: (i) by inhibiting succinic dehydrogenase it prevents the formation of oxaloacetate by the oxidation of isocitrate, with consequent decrease in the amount of acetoacetyl-coenzyme A formed from malonyl-coenzyme A by reaction (9); (ii) malonate causes the loss of acetyl-coenzyme A with formation of free acetoacetate by reaction (15), which is the sum of reactions (14) (ref. 22) and (9):

Malonate + acetoacetyl-coenzyme A ⇌
malonyl-coenzyme A + acetoacetate (14)

Malonyl-coenzyme A + acetyl-coenzyme A →
acetoacetyl-coenzyme A + coenzyme A + CO_2 (9)

Malonate + acetyl-coenzyme A →
acetoacetate + coenzyme A + CO_2 (15)

it would be necessary to determine the exact reasons for the different spectra of the *cis* and *trans* isomers of 4-methylproline, which in turn requires a detailed analysis of these very complex spectra Further research in this direction is in progress

RELATIONSHIP BETWEEN OXIDATION OF ISOCITRATE AND METABOLISM OF FATTY ACIDS IN RABBIT-HEART SARCOSOMES

By Dr W C HULSMANN

Laboratory of Physiological Chemistry, University of Amsterdam

In the presence of adenosine triphosphate (ATP) and [^{14}C]acetate, the oxidation of intermediates of the Krebs cycle by rabbit-heart sarcosomes (mitochondria) is linked with the incorporation of acetate into the mitochondrial long-chain fatty acids[1] It has now been found that two closely related but separate mechanisms are involved, one associated with the oxidation of α-ketoglutarate, succinate or malate and the other with the oxidation of isocitrate The two mechanisms are additive The first is completely sensitive to antimycin and the second is insensitive Since the first step of fatty acid synthesis is the condensation of malonyl-coenzyme A with acetyl-coenzyme A (ref 2), it is thought likely that the Krebs-cycle intermediates provide β-keto carboxylic acids (oxalo-acetate for the first mechanism, oxalosuccinate for the second) for reaction with acetyl-coenzyme A to form malonyl-coenzyme A (cf ref 3)

$$\text{Oxaloacetate} + \text{acetyl-coenzyme A} \rightleftharpoons \text{pyruvate} + \text{malonyl-coenzyme A} \qquad (1)$$

$$\text{Oxalosuccinate} + \text{acetyl-coenzyme A} \rightleftharpoons \alpha\text{-ketoglutarate} + \text{malonyl-coenzyme A} \qquad (2)$$

It is known that isolated heart sarcosomes oxidize added citrate or isocitrate very slowly[4,5] During the investigation of the incorporation of acetate into long-chain fatty acids linked with the oxidation of isocitrate, it was found that the addition of acetate stimulated about six-fold the rate of uptake of oxygen with isocitrate as substrate, and that dinitrophenol abolished this stimulation Measurements of the disappearance of the Krebs-cycle tricarboxylic acids [$-$ Δ(isocitrate + citrate + aconitate)] confirmed that these effects on uptake of oxygen reflected the oxidation of isocitrate

Table 1 shows that a number of other compounds are also able to stimulate the oxidation of isocitrate, namely, β-hydroxybutyrate, α-ketoglutarate, succinate, malate, glutamate or diphosphopyridine nucleotide (DPN) in very high concentrations The effects of α-ketoglutarate and β-hydroxybutyrate, of α-ketoglutarate and acetate, and of diphosphopyridine nucleotide and acetate were not additive Dinitrophenol inhibited the effects of all these compounds except that of diphosphopyridine nucleotide (Table 1 shows that the stimulation by diphosphopyridine nucleotide was the same in the presence and absence of dinitrophenol) Malonate inhibited the stimulation by acetate or β-hydroxybutyrate, but had little effect with α-ketoglutarate (the effect of malonate on the stimulation brought about by the other compounds was not tested)

The measurements shown in Table 1 were carried out under the same conditions as used in work on the incorporation of acetate into long-chain fatty acids[1], that is, in the presence of triphosphopyridine nucleotide (TPN), coenzyme A and adenosine triphosphate, and in the absence of hexokinase and glucose In a reaction mixture commonly used for investigations of oxidative phosphorylation (that is, no added pyridine nucleotide or coenzyme A, adenosine diphosphate in place of the triphosphate and added hexokinase and glucose), neither acetate nor β-hydroxybutyrate had any appreciable effect on the disappearance of isocitrate α-Ketoglutarate stimulated the disappearance substantially, and this stimulation was not affected by malonate It appears, then, that adenosine triphosphate is necessary for the stimulation of the oxidation of isocitrate by acetate or β-hydroxybutyrate, but not by α-ketoglutarate

It is known[6,7] that heart sarcosomes, previously depleted of pyridine nucleotide by incubation in phosphate, oxidize isocitrate in the presence of added pyridine nucleotide by the sequence

$$\text{Isocitrate} + \text{TPN}^+ \rightarrow \alpha\text{-ketoglutarate} + \text{CO}_2 + \text{H}^+ + \text{TPNH} \qquad (3)$$

$$\text{TPNH} + \text{DPN}^+ \rightleftharpoons \text{TPN}^+ + \text{DPNH} \qquad (4)$$

$$\text{DPNH} + \tfrac{1}{2}\text{O}_2 + \text{H}^+ \rightarrow \text{DPN}^+ + \text{H}_2\text{O} \qquad (5)$$

Klingenberg and Slenczka[8] have shown, however, that in rapidly respiring intact mitochondria the diphosphopyridine nucleotide is largely oxidized while the triphosphopyridine nucleotide is largely reduced, suggesting that the accessibility of intra-mitochondrial TPNH to DPN+ to one another or to the pyridine nucleotide transhydrogenase is limited This is probably the reason for the poor oxidation of isocitrate by isolated mitochondria

The stimulation of the oxidation of isocitrate by diphosphopyridine nucleotide can be simply explained by assuming that high concentrations of this compound are able to break the accessibility barrier and

the spectra (Figs 2*b* and *c*) of the *cis* and *trans*-4-methylprolines, provides an indication of its possible stereochemistry (After this part of the work was complete, we were informed by Prof F C Steward and K Biemann that they had reached a similar conclusion by mass spectrometry[11] Their results were considered to favour a *trans* configuration) Thus the 4-hydroxy-4-methyl structure (VI) is immediately eliminated, since no methyl peak is found, and the spectrum agrees very well with the 4-hydroxymethyl alternative (V) In particular, the doublet of intensity two protons at 6 57 is characteristic of a —CH—CH_2—O— fragment, and the peaks at 5 99, 7 6 (approximately) and 8 37, and 6 66 and 6 98 fall in the expected ranges for the H_2, H_{3a} and H_{3b} and H_{5a} and H_{5b} protons of the proline ring Thus all the main groups in the spectrum are consistent with the proposed formula, and define both the nature of the substituent and its position of attachment to the proline ring

The spectrum of (V) (Fig 2*a*) shows very marked similarities with that (Fig 2*b*) of the *cis*-4-methylproline (III) in both the structure of the H_2 peak and the relative chemical shifts of the H_3 protons, which are quite different (Figs 2*b* and *c*), for the two epimeric 4-methylprolines (III) and (IV) This may be considered some support for the assignment of a *cis* configuration to natural 4-hydroxymethylproline (V) (This result is unexpected since it is the *trans* isomer of 4-methylproline which occurs alongside 4-hydroxymethylproline in apple and pear juices [1]) However, it should be emphasized that to confirm this statement

(The synthesis of *trans*-4-methyl-L-proline, which is identical with the natural amino-acid from apple and pear juices, has already been described[1]. A modification of this synthesis has now yielded *cis*-4-methyl-D-proline, enantiomeric with the amino-acid previously isolated from an antibiotic[5]. Full details of this synthetic work will be submitted for publication in the *Journal of the Chemical Society*.)

All the amino-acids were examined as zwitterions in deuterium oxide solution on a Varian spectrometer operating at 60 Mc./s., using dioxan as an internal reference (τ = 6.43). The results are summarized in Table 1 with the nomenclature that *a* and *b* refer to protons on the opposite and the same side respectively of the ring as the CO_2^- group.

The compounds all give complex spectra, some of which have not been fully analysed. The coupling constants obtained from these latter spectra are simply first-order values, that is, they are the actual spacings between particular peaks in the spectrum. Such an analysis only gives approximate values of these coupling constants, which may be in error by as much as 1 c.p.s. in some cases. However, the spectra of the two hydroxy-L-prolines were completely analysed[6], to give all the coupling constants between adjacent protons around the ring. The values of these coupling constants vary from 1 to 10 c.p.s. (Table 1). Both these compounds show, in addition, a long-range coupling over four bonds, between one 3-proton and one 5-proton. The variation of adjacent coupling constants has been explained[7] by means of equation (1)

$$J = K_1 \cos^2\varphi + K_2 \qquad (1)$$

relating the coupling constant J to the dihedral angle φ between the relevant C—H bonds, which in turn depends on the precise conformation of the molecule in solution. (The factor K_2, which was predicted to be very small, will be ignored henceforth.)

In each of the two compounds we have three pairs of coupling constants J_{2-3}'s, J_{3-4}'s and J_{4-5}'s. Each pair, using (1), will give the K_1 and φ for this particular fragment. Only two φ's are necessary to determine the conformation of the molecule. The value of the third pair of couplings thus serves as a test of the applicability of the Karplus equation (1) to the molecule considered.

In the case of the *trans* hydroxyproline the conformation shown in Fig. 1 satisfactorily explains all the observed constants for an angle of buckle of 50–60°. This is an envelope conformation, analogous to the C_s form of cyclopentane[8]. The Karplus equation (1) was derived assuming sp^3 hybridization of the carbon atoms concerned. For the above angle of buckle, the C—C—C angles decreased to around 100°. Thus both equation (1) and the angle of buckle may well be only approximate in this case. However, these results certainly suggest that the molecule exists in solution in a single conformation which is considerably more buckled than has been realized previously.

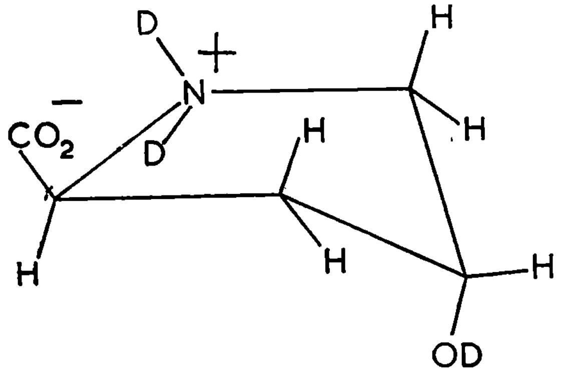

Fig. 1

In the conformation suggested here the OH group attains a pseudo axial configuration while the larger CO_2^- group attains a pseudo equatorial position. (The molecular plane should be considered more correctly as defined by centres 1, 2 and 5 than by centres 1, 2, 3 and 5 (ref. 8).) Presumably the influence of the larger substituent group is the dominant factor.

It is of interest to note that the conformation of the molecule in solution differs from that in the solid, in which a similar type of conformation is found but the angle of buckle is now only 20° (ref. 9).

In the case of the *cis* (allo) hydroxyproline, we now find that there is no single conformation which will predict, by applying equation (1), the observed coupling constants. One possible explanation of this is that the molecule exists in more than one conformation in solution. These conformers would be interchanging rapidly and the observed J's would then be averages of the J's of the particular conformers. Two factors tend to oppose this. Such an averaging process would normally tend to equalize all the coupling constants. Secondly, the long-range coupling would be either averaged out or found on both C_3 and C_5 protons. None of these predictions is observed.

One other possibility is that the Karplus equation (1) does not hold for this molecule, for example, a strong hydrogen bond between the OH and carboxyl groups may distort the C—C—C angles even more than in the *trans* hydroxyproline, in which case the Karplus equation may no longer apply. The formation of an internal lactone in derivatives of allohydroxyproline[10] does suggest that the ring can be considerably deformed.

Whatever the true reason for this discrepancy, two factors emerge from this investigation. First, the observed J's in the allohydroxyproline molecule strongly suggest that the molecule exists in solution in a considerably buckled conformation, or conformations. Secondly, the Karplus equation can give in certain cases information on the precise conformation of molecules in solution, which is extremely difficult to obtain by any other technique, but the results obtained by the application of this equation to other molecules, particularly those which may be expected to occur in a highly strained form, must be considered with some caution.

Although the remaining spectra considered here are too complex for complete analysis, they still provide some further information. In particular, the spectrum (Fig. 2*a*) of the naturally occurring proline derivative (V) or (VI) allows an unambiguous decision in favour of the former, and considered in relation to

where L_i is the measured length of the n_i particles in row i and N is the total number of particles which are measured, the sum being taken over all rows R. The standard error of the mean, S.E.$_{\bar{x}}$, is estimated by:

$$(\text{S.E.}_{\bar{x}})^2 = \frac{\Sigma \frac{1}{n_i} (L_i - n_i\bar{x})^2}{N(r-1)} \tag{3}$$

where r is the number of different row-lengths measured. The standard deviation σ_x of the values for apparent particle diameter is given by:

$$\sigma_x^2 = N(\text{S.E.}_x)^2 \tag{4}$$

For each latex, the error of measurement was estimated independently from repeated measurements on a pair of adjacent particles, and found to be about 80 mμ, although increasing slightly for the largest and smallest particles. These errors are about an order of magnitude greater than those obtained for the mean diameters, demonstrating the efficiency of the array method.

The array method leads to significantly lower values for the 0·8μ and the 1·1μ particles when compared with the electron microscope values[1]. This might be due to an increase in cross-sectional area because of flattening of the particles in the electron beam; such increases are observed for larger particles (Vanderhoff, J. W., personal communication). It is likely that refinement of this method through the use of photographic enlargements will yield even smaller mean diameters for these particles, since fault-lines now indiscernible may be recognized. It should be noted also that the measurement of particles in arrays leads to stratified sampling, disregarding the rare, very large or very small particles; thus, minor components of the distribution are rejected. But, in consequence, the reproducibility of this method is greater than would be expected under random sampling. The array method is, in principle, extendable to investigations of the variation of spherical viruses and macromolecules in crystalline arrays.

This work was performed under the auspices of the U.S. Atomic Energy Commission.

AND

L. F. BURROUGHS

Agricultural Research Station, Long Ashton, Bristol

THE importance of proton magnetic resonance spectroscopy as an aid to the determination of the molecular structures of organic compounds is now well established. One purpose of this article is to show that, in addition, this technique may well prove to be of equal value in the determination of the conformations of molecules in solution.

The compounds examined in this investigation were all C_4 substituted derivatives of proline, namely, *cis* (allo) (I) and *trans*-hydroxyproline (II), *cis* (III) and *trans*-4-methylproline (IV), and a naturally occurring proline derivative for which the alternative structures 4-hydroxymethyl (V) or 4-hydroxy-4-methylproline (VI) have been suggested[3–5].

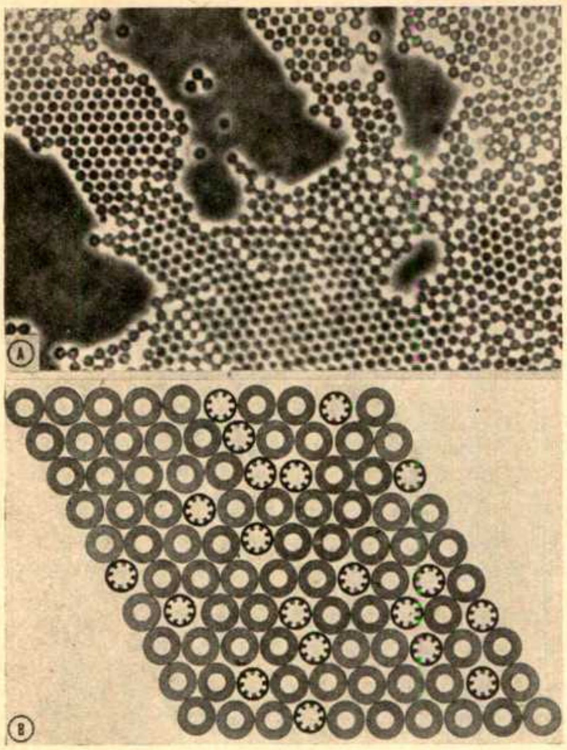

Fig. 1. *A*, arrays of 1·15μ polystyrene particles in oil. *B*, a standard two-component washer array

row is that errors arising from diffraction can be made negligible by choosing the line of symmetry between the diffraction images of the particles, or alternatively, measuring between the centres of two particles. The contribution of error of measurement is further reduced, of course, by spanning a number of particles in the row in a single measurement; variations in particle diameter tend to cancel one another, usually giving an improved estimate of the mean diameter. However, the cancellation is imperfect since a small particle may be only loosely encircled by its neighbours. Thus, a measurement which spans one of these small particles will give a result which over-estimates the true mean.

Simple models indicate that the over-estimate $\Delta\bar{x}$ of the mean diameter should be proportional to the standard deviation σ of the measured distribution of apparent particle diameters:

$$\Delta\bar{x} = k\,\sigma, \quad k = \text{constant} \qquad (1)$$

Thus, a knowledge of the value of k will allow an estimate, D, of the true mean diameter from the apparent mean diameter $\bar{x}$; that is, $D = \bar{x} - \Delta\bar{x}$. It should be possible to calculate k for the triangular arrays shown in Fig. 1, but to my knowledge this problem is unsolved.

The coefficient k was determined empirically from measurements with a vernier caliper of two-dimensional triangular arrays of machinists' washers of known diameters arranged in the rhombic pattern shown in Fig. 1*B*. Two-component arrays, as in Fig. 1*B*, were formed of eighty $\frac{1}{2}$-in. diameter washers with twenty slightly smaller washers added at random locations. The twenty rows of ten washers parallel to the edges of the rhombus were measured to obtain the apparent mean diameter $\bar{x}$, which was then compared with the known true mean to give $\Delta\bar{x}$. Fig. 2 displays the values obtained in this manner for $\Delta\bar{x}/\bar{x}$ and the corresponding values for $\sigma/\bar{x}$ for several two-component arrays, for one array constructed of three sizes of washers (three-component) and for six arrays formed from washers especially constructed to have a normal distribution of diameters (coefficient of variation = 2·36 per cent). These (array sample) values have been fitted with a straight line by least mean squares; the data are consistent with equation (1) giving $k = 0·461$ (S.E., 0·029). This value for k is directly applicable to the triangular arrays of spherical polystyrene particles even though these particles probably are tangent to a glass surface, removing their centres from a common plane. In this case the mean diameter is under-estimated approximately by the fraction $\frac{1}{4}(\sigma/\bar{x})^2$, which would have a value of about 0·01 per cent for the smallest three latexes in Table 1 according to the values of Bradford and Vanderhoff[1].

The formation of arrays from polystyrene latexes has been somewhat unpredictable. With the aid of a wire loop, a minute volume ($\sim$ 1 μl.) of a latex (kindly supplied by Dr. John Vanderhoff, Dow Chemical Co.) was added to a drop of microscope immersion oil (Cargille's; index of refraction, 1·515) on a microscope slide and mixed gently, and a cover-slip was added with moderate pressure. Close-packed triangular arrays of spheres in single layers were found in some of these preparations. Measurements of these arrays were made with a phase microscope ($\times$ 970) having an ocular reticle calibrated to 0·3 per cent. The results of these measurements, summarized in Table 1, appeared independent of the number of particles in the array, with the possible exception of the 0·5μ particles for which arrays of more than twenty particles were not obtainable.

For each latex the apparent mean diameter was determined from:

$$\bar{x} = \frac{\Sigma L_i}{N} \qquad (2)$$

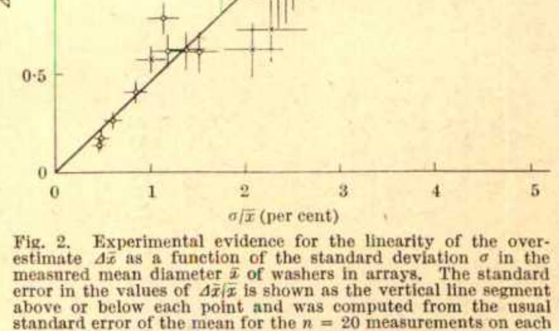

Fig. 2. Experimental evidence for the linearity of the over-estimate $\Delta\bar{x}$ as a function of the standard deviation σ in the measured mean diameter $\bar{x}$ of washers in arrays. The standard error in the values of $\Delta\bar{x}/\bar{x}$ is shown as the vertical line segment above or below each point and was computed from the usual standard error of the mean for the $n = 20$ measurements on each array. The corresponding horizontal line segments at either side of each point represent the estimated standard deviation of σ. The slope of the least mean square line is $k = 0·461$ (S.E., 0·029). ○, Two-component distribution; □, three-component distribution; $\times$, normal distribution. S.E.$_{\Delta\bar{x}} \simeq \frac{\sigma}{\sqrt{n}}$; $\sigma_\sigma \approx \frac{\sigma}{\sqrt{2n}}$

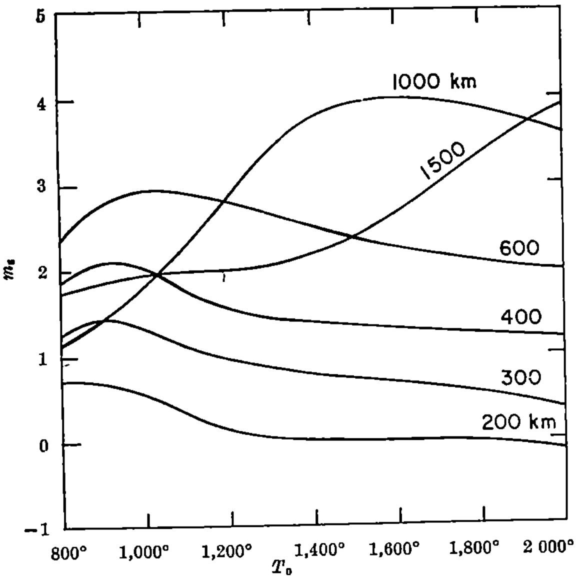

Fig 2 Curves showing the variation of m_0 (= d log ρ_0/d log F) with temperature in the night-time atmosphere for six representative heights

Curves of m_0 for six representative heights are shown in Fig 2 The increase of m_0 with height is evident in the range 200–600 km , at greater heights the picture is distorted by the increasing predominance of helium

The curves of Fig 2 are valid only for the anti-bulge point For any other point, where the temperature is $T = \alpha T_0$ and the density at a given height is ρ

$$m = \frac{\mathrm{d}\log\rho}{\mathrm{d}\log F} = \frac{T - 555\alpha}{T - 555}\, m_0 \qquad (4)$$

Since $\alpha > 1$, m is always smaller than m_0 for a given temperature Considering that the general tendency of m_0 is to decrease with increasing temperature, we can easily see that the parameter m is considerably smaller in the diurnal bulge, compared with its value in the night-time atmosphere

Table 1 Observed and Computed Values of m

Height	Satellite	Time	Observed m	Calculated m
350 km	1958 α	Day	0 75 ± 0 2	0 6
		Night	1 05 ± 0 2	1 1
650 km	1958 $\beta 2$	Day	1 2 ± 0 3	1 2
		Night	3 0 ± 0 4	3 0
1,300 km	1960 $\iota 1$	Day	2 0 ± 0 4	2 2

Priester's observed values of m are predicted almost exactly by Nicolet's model and equation (1), as can be seen from Table 1.

Lastly, Nicolet's model can correctly predict the observed increases of atmospheric density which accompany magnetic storms As was pointed out by me[5,6], these atmospheric perturbations are nearly independent of geomagnetic latitude and occur simultaneously all over the globe Accurate accelerations, as yet unpublished, computed by me in collaboration with Mr J Slowey, show that magnetic storms of comparable intensity give rise to larger drag perturbations when the background drag of the satellite is lower, either because of lower solar flux or because of greater angular distance of the perigee from the diurnal bulge This is what would occur in Nicolet's model atmosphere if as a consequence of the corpuscular storm the temperature of the upper atmosphere were raised by the same amount all over the globe. A fair quantitative representation of all the observed atmospheric perturbations can be given by assuming that the temperature of the upper atmosphere is augmented by an amount ΔT proportional to the geomagnetic planetary index a_p, according to the relation

$$\Delta T = 1\ 5^\circ\, a_p \qquad (5)$$

This equation represents quite well also a number of smaller atmospheric perturbations in March and April 1961, revealed by the ultra-sensitive satellite 1961 $\delta 1$ (the 12-ft balloon satellite)

Equations (1), (2) and (5) provide the means for computing temperatures of the upper atmosphere, for which Nicolet's model gives all other parameters All three equations are only rough outlines of the true relations between the respective variables and should be susceptible of considerable refinements in the future, also, other effects on the atmospheric temperature should be revealed in the more detailed analysis which is now being made It should be apparent, however, that Nicolet's model will provide an adequate basis for such an analysis, as had been expected by its author

OPTICAL CALIBRATION OF SOME MONODISPERSE POLYSTYRENE LATEXES IN ARRAYS

By Dr HERBERT E KUBITSCHEK

Division of Biological and Medical Research, Argonne National Laboratory, Argonne, Illinois

The monodisperse polystyrene latexes, which have been used widely by electron microscopists as secondary standards, have been calibrated in a variety of ways, chiefly by electron microscopy of single particles[1] and light scattering from suspensions[2]. These methods are tedious, and their results have afforded little or no applicability to optical microscopy It seemed possible that arrangements of spherical monodisperse particles in arrays might permit rapid and precise determination of their mean diameters, since a number of particles could be included in a single measurement

The existence of an array of particles, as in Fig 1*A*, is evidence for their uniformity, their contiguity, and the linearity of their rows For microscopic particles, the greatest advantage of measuring particles in a

A WORKING MODEL FOR THE UPPER ATMOSPHERE

By LUIGI G. JACCHIA

Smithsonian Institution Astrophysical Observatory, Cambridge, Mass.

NICOLET[1] has recently published a tabulation of atmospheric densities at altitudes of 150–2,000 km., computed from a model based on diffusion equilibrium with known boundary conditions at 120 km. and with helium diffusion starting at 105 km. The tabulation is given for 12 asymptotic temperature values, ranging from 773° K. to 2,133° K. Assuming the validity of such a model, it is possible to compute upper-atmospheric temperatures directly from densities derived from satellite accelerations, and—since the variation of the density is related to the variation of the decimetric solar flux[2,3]—it appears possible to establish a correspondence between the solar flux and the asymptotic temperature of the upper atmosphere.

For a specific value of the solar flux the temperature in the upper atmosphere ranges from a maximum at the centre of the diurnal bulge[3] to a minimum in the dark hemisphere. Unless we know accurately how the temperature varies with the location of a point in the atmosphere with respect to the bulge, we cannot reduce the temperatures derived from satellite accelerations to a standard location. Since, however, the variation of temperature appears to be quite small within a radius of at least 50° around the anti-bulge point[3], that is, the point 180° from the centre of the bulge, we can take satellite accelerations obtained within that region and establish for them a correspondence between solar flux and temperature. Results from four satellites are plotted in Fig. 1. The good inner agreement of the individual points, irrespective of satellite height, shows that Nicolet's model appears quite satisfactory. The relation between the minimum night-time temperature T_0 and the solar flux F at 10·7 cm. appears to be linear within the observed accuracy, the straight line in the diagram corresponds to the equation

$$T_0 = 555° + 3° \; F \tag{1}$$

where T_0 is expressed in °K. and F in units of 10^{-22} W./m.^{2}/cycle/sec.

The accelerations of the four satellites from which this relation was derived extend over the interval February 1958–March 1961, during which the 10·7-cm. flux varied from a maximum close to 350 F units to a minimum of about 90, covering about 90 per cent of the expected range during the present 11-year solar cycle (the 1954 minimum was about 70, and it can be confidently expected that a similar reading will prevail in 1964–65). Atmospheric densities in the bulge can be represented with Nicolet's model, assuming that the temperature T_M at the centre of the bulge is in a constant ratio

$$T_M = 1{\cdot}35 \; T_0 \tag{2}$$

to the night-time temperature T_0.

The decay of the temperature from the centre of the bulge outward will require a more refined analysis which is not yet completed. In my 1960 model, I (ref. 3) assumed that the density at a given height varied as $\cos^6 \frac{\psi'}{2}$, where ψ' is the angular distance from the centre of the bulge. On the basis of Nicolet's model it appears that for height under 700 km. the bulge must become sharper with increasing height, and this is corroborated by the comparison of recently obtained accelerations of satellites 1958 α (perigee height 350 km.) and 1958 $\beta 2$ (perigee height 600 km.). In addition, the shape of the bulge must vary with the solar flux, only an analysis of temperatures through the bulge seems likely to yield satisfactory results.

In my 1960 atmospheric model[3] it was assumed that the atmospheric density ρ for any given height and any given ψ' is proportional to F^m, for simplicity it was assumed that m = constant = 1. Recently, Priester[4] found that m increases with height and is larger in the night-time atmosphere than in the sunlit hemisphere. It is interesting to note that this result can be deduced directly from Nicolet's model, if we assume that the relation between F and T_0 is given by equation (1). Calling ρ_0 the night-time density at a given height in the atmosphere, we shall have:

$$m_0 = \frac{d \log \rho_0}{d \log F} = \frac{T_0 - 555}{T_0} \; \frac{d \log \rho_0}{d \log T} \tag{3}$$

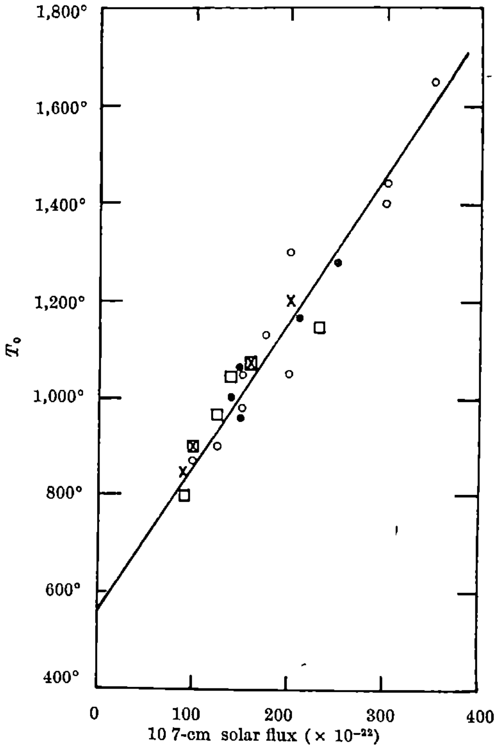

Fig. 1. Relation between the 10·7-cm. solar flux and the night-time temperature of the upper atmosphere, derived from four satellites using Nicolet's atmospheric model.

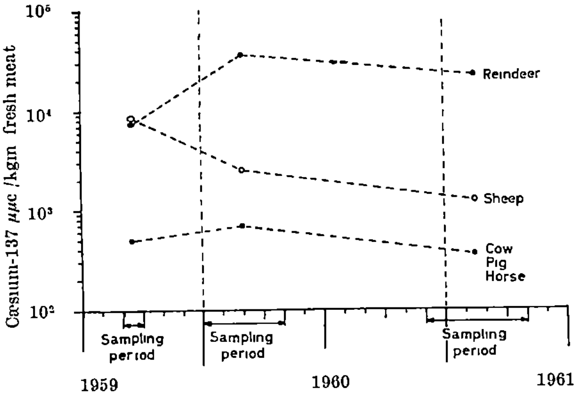

Fig 3

by a yearly precipitation of about 300 mm The total strontium-90 fall-out in Norway may be estimated from Fig 2 *B* to be approximately 5,500 c. at the end of June 1959, of which about 30 per cent may be dry fall-out. Adding 4 9 mc /km.^{2} found as the increment for Bodø from June 1959 to September 1960 (Fig 1 *D*, the mean annual precipitation at Bodø being near the average for Norway), the total strontium-90 fall-out at the end of September 1960 may be estimated to be about 7,000 c. The ratio of cæsium-137 in soil to strontium-90 in soil, both as estimated, is about 1·7

Cæsium-137 in meat was measured during 1959, 1960 and 1961 The results are

	1959	1960	1961	
Cow, pig, horse	2 samples	31 samples	38 samples	
Average value	500	700	400	μμc cæsium-137/kgm fresh meat
Maximum ,,	600	2,800	1,500	,, ,,
Minimum ,,	300	200	~0	,, ,,
Sheep	2 samples	12 samples	9 samples	
Average value	8,000	2,500	1,200	μμc cæsium-137/kgm fresh meat
Maximum ,,	11,000	9,000	3,000	,, ,,
Minimum ,,	5,000	50	100	,, ,,
Reindeer	2 samples	6 samples	48 samples	
Average value	7,700	35,000	22,000	μμc cæsium-137/kgm fresh meat
Maximum ,,	9,300	56,000	37,000	,, ,,
Minimum ,,	6,200	16,000	7,000	,, ,,

The results are plotted in Fig 3 The level found in the fall of 1959 is uncertain due to the very limited number of samples measured. During 1960–61 there appears to be a decrease of about 50 per cent in cæsium-137 concentration in all three groups of animals It appears that, on the average, the uptake of cæsium-137 by sheep is about five times higher than by cow, pig and horse The uptake by reindeer is about ten times higher than by sheep. As this difference is apparently not due to a difference in fall-out amounts, it seems reasonable to relate it to different grazing habits and different grazing field qualities Within each group of animals there is a difference from district to district that may be related partly to differences in amounts of fall-out and partly to differences in conditions of grazing. There does not appear, however, to be any large difference in concentration of cæsium-137 in reindeer from southern Norway and northern Norway The samples collected in 1961 were also analysed for potassium The average values are

Reindeer	4 4	gm potassium/kgm fresh meat
Sheep	3 2	,, ,,
Cow, pig horse	3 0	,, ,,

It appears that the potassium content in reindeer is about 40 per cent higher than in sheep, cows pigs and horses

Strontium-90 in animal bones from Norway has been measured by HASL, United States Atomic Energy Commission, New York Operations Office The results are

	1954 summer	1956 autumn	1958 autumn	
Cow	2 samples			
Average value	0 5			μμc strontium-90/gm calcium
Maximum ,,	0 8			,,
Minimum ,,	0 2			,,
Sheep	5 samples	14 samples		
Average value	4	17		μμc strontium-90/gm calcium
Maximum ,,	7	34		,,
Minimum ,,	2	6		,,
Reindeer		4 samples	10 samples	
Average value		100	150	μμc strontium-90/gm calcium
Maximum ,,		120	250	,,
Minimum ,,		40	110	,,

The four samples of reindeer bones collected in 1956 were analysed at the Atomic Energy Research Establishment, Harwell The reindeer bones collected in 1958 were also analysed for strontium-89 The results are

	Northern Norway	Southern Norway	
	4 samples	6 samples	
Average value	610	40	μμc strontium-89/gm calcium
Maximum ,,	650	94	,,
Minimum ,,	540	17	,,

The reindeer from southern and northern Norway were of comparable age and the samples collected at the same time The difference in concentration of strontium-89 may then indicate a difference in time of arrival of strontium-89, or different grazing conditions giving a difference in delay of uptake of strontium-89

In good agreement with the results for cæsium-137, it appears that the uptake of radioactive strontium by sheep is higher than that by cows, and the uptake by reindeer is higher than that by sheep The relatively high uptake by reindeer may be related to the special grazing habits of this animal Reindeer feed to a great extent on the slow-growing lichen The uptake of fall-out materials by lichen appears to be higher than by other vegetation

Three samples of lichen from northern Norway were measured during autumn, 1959 The results are

Sample	μμc cæsium-137/kgm lichen	mc cæsium-137/km^2
I	42,000	74
II	37,000	56
III	31,000	66
Average	36,000	65

From the yearly precipitation at the sampling place, the total amount of cæsium-137 deposited may be estimated from Fig 2 to be about 60 mc /km ^{2} at the end of 1959 It appears therefore that the efficiency of fall-out retention for lichen is very high

Summarizing, it seems that for internal radiation from fall-out materials the variations in uptake of radioisotopes by animals may be more important than the uneven geographical distribution of fall-out

[1] Crooks, R N , *et al* , Atomic Energy Research Establishment Report *R* 3349 (1960)

[2] Small, S H , *Tellus*, 12, No 3 (1960)

[4] Medical Research Council, *The Hazards to Man of Nuclear and Allied Radiations* (H M S O , London, 1960)

It appears that the maximum yearly cæsium-137 fall-out measured is approximately ten times the minimum. The cæsium-137 fall-out in 1960 was considerably lower than in the three foregoing years. The cumulative cæsium-137 fall-out at Bergen (60° 23′ N, 5° 21′ E) from September 1956 to June 1961 is shown in two-monthly periods by curve *A* in Fig. 1. The total deposition during this period is about 70 mc./km.^{2}. The relatively heavy cæsium-137 fall-out during the period September–October 1957 may be due chiefly to the Windscale accident. Strontium-90 in precipitation at Bodø (67° 17′ N, 14° 24′ E), and Tromsø (69° 40′ N, 18° 57′ E) has been measured by the Atomic Energy Research Establishment, Harwell, as part of a world-wide precipitation sampling programme[1]. The concentration in the total yearly precipitation for the past 3 years has been

	1958	1959	1960	
Bodø	6·2	17	3·8	μμc strontium-90/l. precipitation
Tromsø	5·4	14	2·5	,, ,,

The yearly fall-out was

	1958	1959	1960	
Bodø	7·1	18	2·6	mc strontium-90/km.^{2}
Tromsø	4·2	17	2·2	,, ,,

The cumulative strontium-90 fall-out at Bodø from April 1957 to December 1960 is shown in three-monthly periods by curve *C* in Fig. 1.

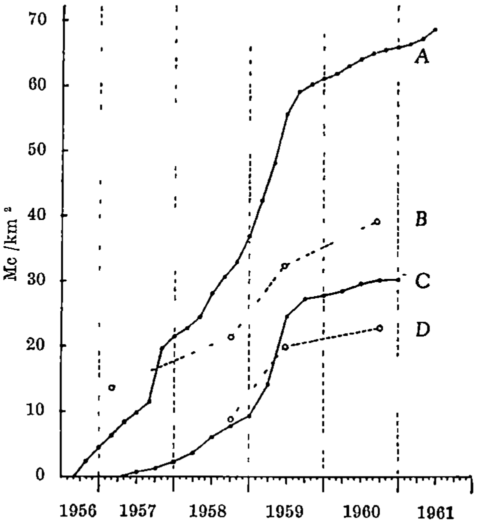

Fig. 1. *A*, Bergen cæsium-137 in precipitation, *B*, Bergen strontium-90 in soil, *C*, Bodø strontium-90 in precipitation, *D*, Bodø strontium-90 in soil

Cæsium-137 in soil was measured at several places in Norway in September 1960. Fig. 2 *A* shows the results plotted versus precipitation during the period from January 1, 1953, to the date of sampling. It appears that fall-out/mm precipitation decreases with increasing precipitation. As indicated in Fig. 2, this may be due to an amount of dry fall-out equal to the fall-out deposited by a yearly precipitation of approximately 400 mm. It follows from this that in Norway the dry fall-out may be about 30 per cent of the total fall-out, the mean annual precipitation in Norway being about 900 mm. This is in reasonably fair agreement with what has been found for Kjeller[2]. The total cæsium-137 fall-out in Norway, which has an area of 324,000 km.^{2}, may be estimated from Fig. 2 *A* to be about 12,000 c at the end of September 1960.

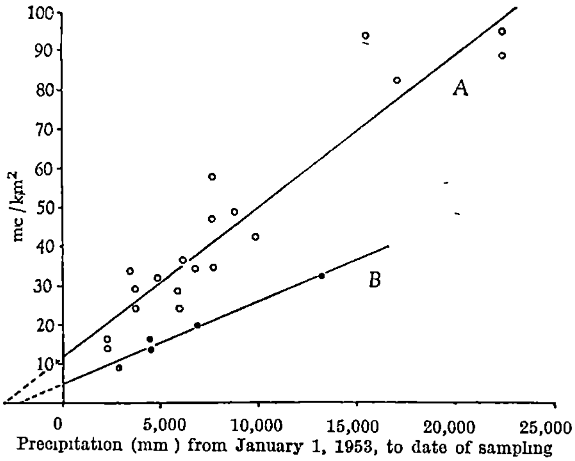

Fig. 2. *A*, cæsium-137 in soil, September 1960. *B*, strontium-90 in soil, June 1959

Strontium-90 in soil has been measured at several places in Norway by L. T. Alexander, as part of a world-wide soil-sampling programme[3]. The results for Bergen are shown by curve *B* in Fig. 1, and the results for Bodø by curve *D*. It appears from Fig. 1 that the strontium-90 fall-out at Bodø as deduced from soil measurements is lower than that measured in precipitation. The ratio is

	Oct. 1958 to June 1959	July 1959 to Sept. 1960	Oct. 1958 to Sept. 1960
Strontium-90 in soil / Strontium-90 in precipitation	0·65	0·88	0·71

The difference might indicate leaching out of the soil or re-suspension of deposited fall-out, but more probably it is an indication of the difficulty involved in obtaining a representative value of the amount of precipitation falling on the ground, especially where snow-drifting occurs during winter. The differences in the sampling and measuring methods may also be important factors. The results for Bergen, shown in Fig. 1, give the following ratio of cæsium-137 in precipitation to strontium-90 in soil

	March 1957 to Sept. 1958	Oct. 1958 to June 1959	July 1959 to Sept. 1960
Cæsium-137 in precipitation / Strontium-90 in soil	3·3	2·0	1·6

The high ratio during the period March 1957–September 1958 seems to agree with the suggestion that the cæsium-137 fall-out during the period September–October 1957 was due chiefly to the Windscale accident, the strontium-90 release of which has been given as less than 1 per cent of the cæsium-137 release[4]. If the cæsium-137 fall-out during this period is excluded, the ratio will be 2·2 instead of 3·3. In view of the different methods of sampling and measurements, the ratio of cæsium-137 to strontium-90 of about 2 seems to indicate that the soil data are in reasonably good agreement with the precipitation data. The measurements by the Atomic Energy Research Establishment, Harwell, give an average ratio of cæsium-137 to strontium-90 in fall-out nearer 1·7 (ref. 1).

Fig. 2 *B* shows strontium-90 in soil-samples collected during June 1959 plotted versus precipitation during the period January 1, 1953, to the date of sampling. In good agreement with the cæsium-137 results in Fig. 2 *A*, the strontium-90 results indicate an amount of dry fall-out equal to the fall-out deposited

for evaluation in the region of the spectrum (2640–4300 Å.) examined silver, aluminium, calcium, cobalt, chromium, copper, iron, potassium, magnesium, manganese, sodium, nickel, lead, silicon, tin, titanium, vanadium, zinc and zirconium

Of these elements the only ones which the spectroscopic evidence proved to be significantly more concentrated in the glaze than in the fabric were silver, lead and tin. The evidence also suggested that the concentrations of copper and vanadium were higher in the glaze, but for these elements the evidence was not unequivocal The use of lead in pottery glazes is, of course, well known, and the presence of tin in medieval glazes has previously been recognized by Jope[6,7] As no reason for the deliberate addition of silver is apparent, it appears probable that this element occurs as an impurity in one of the other additives While lead is the obvious choice for the silver carrier, the relative concentrations of lead and silver fluctuate too widely in closely related glazes for this suggestion to be readily accepted The variation of silver content more closely follows that of the variation of tin, and this may indicate that some alloy or mineral containing both these elements has been added to the glazing material in addition to the galena normally accepted as the source of the lead Both solder and pewter have been suggested by Jope[7] as possible sources of tin in glazes from medieval pottery

The presence, and amount, of tin in the glaze has been used as a check on some of the accepted attributions of origin of the pottery sherds All the samples examined of glaze from Laverstock kilns have a high tin content However, the glazes of sherds found at Winchester and Bergen have low tin contents It appears therefore, that, although the Winchester and Bergen samples are visually similar to those from Laverstock, they are unlikely to have originated from the Laverstock kilns Of those we have examined the only English glaze with a comparable low tin content is that from the Tyler Hill kiln[8] near Canterbury

One group of English glazes and one group of Continental glazes contained no detectable tin This pottery, with the exception of a sample from Oslo, is of an earlier date (eleventh–twelfth century A D) than the remainder (late thirteenth–fourteenth century) The English group comprised three samples of 'Stamford ware', two from excavations at Thetford and one from Peveril Castle, Derbyshire The Continental group comprised four samples of 'Andenne ware', one from an Andenne kiln, one from Antwerp, one from London and one from Canterbury, and the sample from Oslo designated on archæological grounds as 'Nottingham ware' (Dunning, G C , private communication Mr Dunning suggests on typological grounds that this sample came from a kiln in that part of eastern England in the area Nottingham–Scarborough–King's Lynn) This spectroscopic similarity between the glazes of Stamford and Andenne wares is a striking confirmation of the theory put forward by Dunning[9] that the two wares developed from a common origin It is clear, however, from observed differences in the composition of the fabric materials that these samples could not have originated from the same kiln

Although all the Laverstock glazes had high tin contents, the relative amounts of tin and lead in the glaze varied significantly On calculating the ratio of the observed intensities of lead and tin lines in the glaze, this was found to vary from 1 1 to 4 7 Placing the ratios in numerical order arranges the kilns from which the glazes originated in an order very close to the chronological order assigned to these kilns on the basis of archæological evidence, the lowest tin content arising from the earliest kiln It is difficult to envisage any reasons why the tin content of the glazes should have been gradually increased, and it may well be that analyses on further samples will prove that this apparent systematic variation of the lead/tin ratio is fortuitous

Two further points of interest have been noted from the examination of the Laverstock glazes In all the kiln samples the calcium content of the glaze is higher than that of the fabric, suggesting that a calcium compound has been deliberately added, possibly to improve the adhesive properties of the glaze Some of the samples examined had an additional stripe decoration in a darker colour than the body glaze Comparative analyses of the two different coloured glazes from the same pot have revealed that this colour is solely due to the presence of enhanced concentrations of iron

CÆSIUM-137 AND STRONTIUM-90 IN PRECIPITATION, SOIL AND ANIMALS IN NORWAY

By T. HVINDEN and A. LILLEGRAVEN

Division of Physics, Norwegian Defence Research Establishment, Kjeller

FROM fall-out measurements in Norway it seems that in this country the variations from one group of animals to another in uptake of radioisotopes may be greater than the variations in amounts of fall-out from one district to another. The geographical variations in fall-out are indicated by the amounts of cæsium-137 measured in precipitation at twelve places in Norway The concentration in the total yearly precipitation for the past 4 years has been.

	1957	1958	1959	1960	
Average value	5 7	8 9	15	3 2	μμc cæsium-137/l precipitation
Maximum ,,	7 2	11	18	4 4	,, ,,
Minimum ,,	2 7	6 9	9 8	2 5	,, ,,

The yearly fall-out was

	1957	1958	1959	1960	
Average value	6 1	7 6	11	2 3	mc. cæsium-137/$km.^2$

PRODUCTIVITY IN LETTERPRESS PRINTING

THE mounting cost of printing would alone give wider interest to the report on *Productivity in Letterpress Printing*, recently published by the Department of Scientific and Industrial Research*.

The report describes the results of an investigation made during 1956–57 by the Printing, Packaging and Allied Trades Research Association under a contract financed from Conditional Aid Funds and in which eighteen firms collaborated. The organization, methods and production of seventeen firms were examined in detail, and a detailed breakdown of machine time indicated that, on average, machines are only running for about 40 per cent of their manned time. Speed is accordingly not of prime importance: it is usually easier to increase production by reducing delays, make-ready times and other stoppages, and the average speed of new machines with a high potential running speed is little better than that of pre-war machines. What is needed in printing machines at present is the provision of devices to facilitate make-ready, control and adjustment.

The factors responsible for the low running time are discussed in the report, and while in some firms particular operations are inefficient, the greatest improvement can only result from a thorough examination of the printing process as a whole. Waiting time averaged 15 per cent and make-ready time 45 per cent of available time, and although the latter is a necessary and chargeable operation in printing, it can be substantially reduced by improvements in methods and organization. These usually could be made with little capital outlay but require an industrial engineering approach using work-flow principles, greater specialization of work by employees, quantitative measurement and mechanical aids for handling, and the like. At present, for example, so little method study is used that employees can earn bonuses on inefficient and even unnecessary operations, and conditions, as regards lay-out, in most machine rooms are described as chaotic.

The report is also critical of organization, production planning and storage in the industry, where also major changes in procedure are recommended. It is recognized that not all factors influencing efficiency are within the immediate control of printers, but there is scope for more standardization and greater co-operation between printers and other sectors of the industry. Better production planning and greater precision at each stage of the process could effect a real increase in production at lower costs, and a separate chapter in the report outlines the problems requiring further investigation. These chiefly call for operations research and kindred methods, very few purely technological problems came to light.

A SPECTROSCOPIC SURVEY OF ENGLISH AND CONTINENTAL MEDIEVAL GLAZED POTTERY

By L. C. THOMAS and J. W. G. MUSTY

Chemical Defence Experimental Establishment, Porton Down, Nr. Salisbury, England

ONE of us (J. W. G. M.) recently claimed[1] that a medieval glazed jug from Bergen, found during the excavation of the Hanseatic Wharf there[2], had been made in the late thirteenth century kilns at Laverstock, near Salisbury, Wiltshire, England[3]. This and other attributions, based on a visual comparison of pottery sherds, have been checked by the spectroscopic examination of sherds from these sites and from a number of other English and Continental sites. While a range of sites has been covered, the number of samples from any site, other than Laverstock, has been limited. The variation in glaze composition found between samples from different kilns at Laverstock clearly indicates that more samples from each site must be examined for the full value of this technique to be realized. However, this preliminary survey has provided sufficient evidence to enable some conclusions to be drawn.

The pottery samples examined, other than those from Laverstock, were supplied by Mr. Gerald Dunning and included sherds from English kiln sites at Brill (Bucks.), Cheam (Surrey), Ham Green (Glos.) and Tyler Hill (Kent). Pottery found at Winchester and at Clarendon Palace, near Salisbury, was also examined as the kiln sites for these samples are unknown and Laverstock was thought to be one of the possible sources of supply. Examples of pottery attributed to foreign kilns, but found in Britain, included French polychrome ware from Glastonbury and Dover, French pottery found at Bristol, and the Belgian Andenne ware found at London and Canterbury. Samples of Andenne ware from Antwerp and from an Andenne kiln[4] were also examined. Samples found at Oslo and Bergen but attributed to British kilns were also included in this preliminary survey.

Small areas of the glaze were removed from the sherds by careful scraping with a tungsten carbide tipped masonry drill. Samples of the fabric were obtained from the unglazed side of the sherds as a control on the inevitable contamination of the glaze by the fabric. The samples thus obtained were ground in an agate mortar, packed into special 'cathode layer' graphite electrodes, and their spectra obtained and the line intensities evaluated using techniques previously described[5]. The results obtained will be reported in detail elsewhere. No attempt has been made to place these qualitative results on other than a semi-quantitative basis. Variations in the relative concentrations of elements have been assessed by variations in the relative intensities of lines of these elements in the same spectrum. The following elements had lines suitable

Dipicolinic Acid Content, Heat-Activation and the Concept of Dormancy in the Bacterial Endospore

Two distinct meanings have been applied to the use of the term 'dormancy' as applied to the bacterial endospore. First, the expression 'the dormant bacterial endospore' usually describes the apparent metabolic inactivity of the spore stage as compared with the vegetative cell. Secondly, the same term has been used to describe the fact that spore suspensions respond poorly or not at all to germination agents under conditions that permit rapid germination of aged[1] or heat-activated[2] spores. It is in the latter sense that the term dormancy is applied in this communication.

It is difficult to express quantitatively the dormant state of a spore preparation. Recent work suggests that the duration of heat-activation required for optimal germination can be used to measure the process. However, the duration of heat-activation necessary to induce optimal germination is not constant itself and can differ widely for different preparations of the same spore strain. The duration of heat-treatment necessary to induce optimal germination decreases with the age of the spore preparation[1]. L-Alanine-induced germination in *Bacillus cereus*[3] and glucose-induced germination in *Bacillus megaterium*[4] also indicate another relationship. With increasing concentrations of the germinating agents, less heat treatment is required for optimum germination.

In our work the requirement for heat-activation was further related to the chemical composition of the spore and the nature of the germinating agent employed.

Dipicolinic acid content and the germination-rate. The content of dipicolinic acid (DPA) in a spore can be varied by the conditions of growth and sporulation[5-7]. Also, it was observed that if higher concentrations of yeast extract were added to the '*G*' medium[5], the level of spore DPA could be increased from 7 to about 15 per cent of the dry weight. In the present work DPA contents of 2·2–15 per cent were employed.

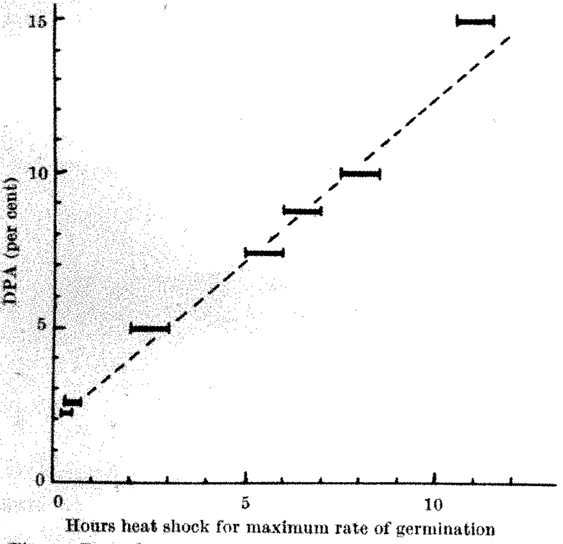

Fig. 1. Dependence of the duration of heat shock on intrasporal DPA concentration. Spores containing various concentrations of DPA were heat-shocked for various periods at 65° C., centrifuged, washed and resuspended in *M*/50 *tris* buffer *p*H 8 to an optical density of 0·40. Germination at 30° C. was initiated by the addition of 15 mgm./ml. L-alanine. The rate of germination was followed spectrophotometrically, as described by Woese *et al.* (ref. 8). The bars indicate the approximate time of heat-shock required to obtain maximum germination-rates

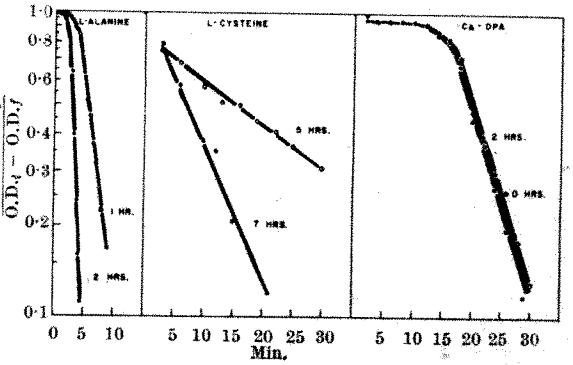

Fig. 2. Effect of heat-shock on the rate of germination in L-alanine, L-cysteine and CaDPA. See Fig. 1 for details of heat-shock and L-alanine-induced germination. L-Cysteine (15 mgm./ml.)-induced germination was followed at 30° C., whereas germination induced by $4 \cdot 8 \times 10^{-3}$ *M* calcium chloride, 4×10^{-3} *M* DPA was carried out at 20° C. in the presence of 0·2 per cent gelatine

When the amount of heat-activation necessary to give optimal L-alanine-induced germination was determined it was found that the extent of heat treatment necessary (65° C. in water) was related to the DPA content. The heat-shock requirements increased with increasing contents of DPA. These results are shown in Fig. 1. The germination-rates obtained with the various spore preparations after optimal heat treatment were constant when the same concentrations of L-alanine were used.

Relationship between the heat-shock requirement and the germinating agent. The effectiveness of L-cysteine as a germinating agent under various conditions of heat-shock and with spores with various DPA contents was identical to that observed with L-alanine. On the other hand, the effect of calcium DPA was quite different. As observed by Rieman and Ordal[9], equimolar Ca^{++} and DPA are effective germinating agents for bacterial spores. The rate of germination in the presence of CaDPA was not influenced by heat-shock treatment or by the endogenous level of DPA. These results, as well as the behaviour of L-alanine and L-cysteine towards heat-shock treatment, are shown in Fig. 2.

DPA release during heat-activation. Harrell and Mantini[10] observed a release of DPA during the heat-activation of spores of *B. cereus* strain *T*. The hypothesis is therefore posed that germination ensues only after the endogenous DPA content is first reduced to a critical threshold. The observations that CaDPA complexes with amino-acids and peptides[11] and the numerous suggestions that dormancy is maintained by endogenous levels of inhibitors[12] are easily explained on the basis of a critical DPA threshold hypothesis. To test this directly with regard to DPA itself, the amount of DPA released after sufficient heat-shock to permit optimal germination was measured in spore stocks with widely varying levels of DPA. The results are shown in Table 1. In all spore stocks examined there was no relationship between the amount of DPA released and germination. Optimal germination occurred with about a 10 per cent loss of DPA. It is possible, however, that several reservoirs of DPA exist, only a minor fraction of which controls dormancy. Before such a possibility can be investigated, more information on the state of spore DPA will be necessary.

The ability to measure quantitatively the degree of dormancy of a bacterial endospore enables one to

Table 1. RELEASE OF DPA FROM SPORE SUSPENSIONS DURING HEATING

DPA content of spore suspension (percentage dry weight)	Heat activation (hr.)	Percentage DPA released during heat activation
14·9	11	10
10·2	9	9
7·4	8	14
4·9	4	9

Spores were grown in modified *G* medium, and heat-shocked as described in Fig. 1. The spores were then centrifuged and the DPA content of the supernatant determined by the method of Jansen *et al.* (ref. 13).

study some of the principal factors regulating dormancy. First, what is the chemical nature of the mechanism regulating dormancy? Although this cannot be answered, the present experiments provide a suggestion that DPA may be a part of the system responsible for the dormant state. If the intrasporal concentration of DPA determines dormancy, the breaking of dormancy cannot be related merely to the removal of DPA. One possibility is that the breaking of dormancy involves an activation stage (heat-activation) and that the achievement of this stage requires the displacement of DPA (or a compound correlated with DPA) from some endogenous site(s).

Secondly, is the dormant state unique? As seen above, the degree of dormancy is dependent on the germinating substance used. For example, high DPA spores are dormant towards L-alanine, and L-cysteine, but not towards CaDPA. The concept of dormancy is, therefore, not a general one, characterizing the state of a given spore suspension, but is relative to the germinating agent.

Thermophilic Micro-organism of Uncertain Taxonomic Status from the Hot Springs of Tiberias (Israel)

IN the course of a survey of the fauna and flora of the hot springs of Tiberias[1], which attain a temperature of 60° C., a bacterium was isolated which shows a special mode of reproduction and apparently has not yet been described.

The mature cells are spherical, ovoid or pear-shaped, measuring 0·5–2μ. They are non-pigmented, non-spore forming and Gram-variable. They occur singly or as free-floating groups of two, three, four or even more individuals, in the form of rosettes and short chains (Fig. 1 *a*, *b*). Daughter cells are formed as buds (Fig. 1 *c*) and appear sometimes to be situated between two larger cells. A low percentage of the solitary forms are motile, these cells possessing a single polar flagellum (Fig. 2).

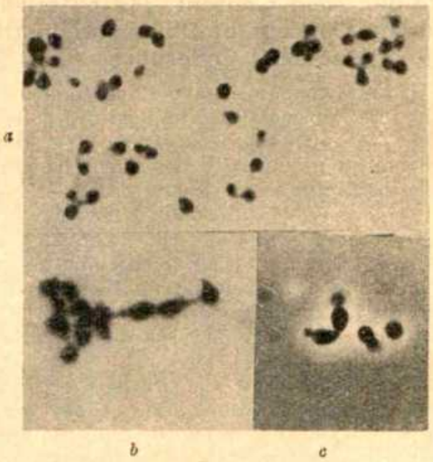

Fig. 1. Micrographs of bacteria. *a*, Single, pair and rosette forms; *b*, a chain form; *c*, budding bacteria. (× 1,500)

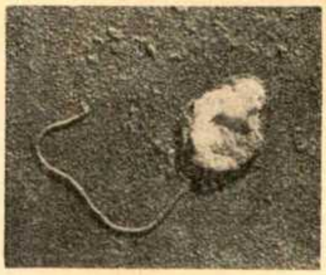

Fig. 2. A motile form possessing a single polar flagellum. Electron micrograph. (× 11,000)

Motility was observed occasionally in groups of two cells, and only in one case in a group of three.

The micro-organisms can be grown in autoclaved water from the hot springs, supplemented with 0·005 per cent yeast extract (Difco). No growth occurred when the concentration of the yeast extract was raised to more than 0·02 per cent. At 50° C. in the dark, the cultures achieved maximum cell density after one day, while at 37° C. they grow slowly and the peak is achieved only after several days. No multiplication occurs at 30° C. The organism is euryhaline and growth occurs over a range of 1–6 per cent (w/v) of total salt concentration; the concentration of minerals normally found in Tiberias hot springs is about 3 per cent[2]. Growth also occurred when spring water was replaced by sea water and supplemented with yeast extract as described here. The range of tolerance to sea water salinity is 0·5–8 per cent (w/v) total salinity. No growth was obtained on a solid agar medium. The highest concentration of agar ('Purified Bacto Agar, Difco') in which multiplication could be obtained was 0·2 per cent. The organism is aerobic as growth appears in a thin top layer of the semi-solid medium. The *p*H tolerance is wide, ranging from 6·2 to 9·5.

The taxonomic position of this micro-organism is as yet uncertain. It undoubtedly belongs to the budding bacteria included in the order Hyphomicrobiales[3]. Unfortunately, the taxonomy of the members of this order is uncertain as most descriptions are based on microscopic examination[4,5].

Further investigations on this interesting micro-organism are being carried out.

CYTOLOGY

Chromosome Preparation from Fresh and Cultured Tissues using a Modification of the Drying Technique

TECHNIQUES for making satisfactory chromosome preparations have evolved rapidly during the past decade since Makino and Nishimura[1] and Sachs[2] adopted pre-treatment with hypotonic solutions and the squash method of preparation. Administration of colchicine increased the number of countable mitoses and facilitated analysis by arresting cell division in metaphase, producing shortening of chromosomes and divergence of sister chromatids.

The Feulgen squash method[3] has been used widely for chromosome preparations. Although adequate in many instances it has several disadvantages. (1) Firm and even pressure is not easy to achieve, and areas of insufficient or excessive squashing are difficult to avoid. (2) Nuclei with incomplete or broken chromosomes are found in an appreciable number of cases. Tough *et al.*[4] reported 22 per cent of incomplete groups in their countable material. This complicates analysis. (3) Valuable material may be lost during squashing around the edges of the coverslip—an important factor, if small quantities only are available for analysis.

The drying technique for chromosome preparation was introduced by Rothfels and Siminovitch[5]. Spreading of chromosomes is achieved by alteration of surface tension forces involved during drying on the wet slide. The method has been reported on favourably by Moorhead *et al.*[6] and Tough *et al.*[4], the latter reporting that out of all countable groups 96 per cent were unbroken in their preparations. The technique was, however, only suitable for relatively fragile nuclei such as that from cultured human leucocytes. In human bone marrow and animal material, that is, bone marrow, spleen, lymph glands, etc., squashing was usually necessary.

A method of achieving satisfactory chromosome preparations by the drying technique has been evolved which can be applied to both human and animal tissues. Besides human cultured leucocytes, good-quality preparations have been obtained from marrow and spleen of mice, rats and rabbits. The technique is reliable, relatively simple, incurs minimal loss of material and produces a high count of unbroken and well-spread chromosome groups.

After pre-treatment with 'Colcemid' either *in vitro* in the case of cultures, or *in vivo*, a cell suspension is prepared (solid tissues are homogenized) and incubated with 0·95 per cent sodium citrate solution at 37° C. for 30 min. The following scheme is then followed. The suspension is centrifuged at 200*g* for 5 min. in Kahn tubes and the supernatant fluid is removed. Fixative (3 parts absolute alcohol to one part glacial acetic acid) is added and changed after 5 min. without disturbing the layer of cells lying at the bottom of the tube. The preparation is kept in iced water or a refrigerator at 4° C. for 1 hr. The fixative is removed and chilled 45 per cent acetic acid is added. The tubes are kept in a refrigerator for 18–24 hr. The 45 per cent acetic acid is removed and chilled 60 per cent acetic acid is added and the preparation kept cool for 1 hr. Only then are the cells resuspended in the 60 per cent acetic acid, so as to make a concentration of approximately 15×10^6 cells per ml. A microscope slide is placed on a flat piece of solid carbon dioxide and kept in place until a white film of frozen condensation forms on its upper surface. The slide is lifted and held obliquely until thawing has just begun at the edges. Small drops of the suspension are then placed on the frozen surface. The drops must not freeze on the slide but should spread rapidly, the cells adhering to the surface of the slide. The slide is then immediately heated over a spirit lamp, very gently if the material was obtained from cultured human leucocytes or more strongly in the case of other cells. The degree of heating may involve some trial and error, but in the case of mouse spleen cells, for example, it should be more rapid, so that drying is accomplished within several seconds, the temperature of the slide being above that tolerated by the back of the hand. Staining is performed with aceto-orcein.

The method produced satisfactory spreading of chromosomes in both fresh and cultured material. It was equally successful in preparations from marrow and solid tissues. The number of countable groups of chromosomes was considerably higher than in corresponding preparations by the squash technique. A large number of countable and clearly spread mitoses was obtainable on one slide. In the case of chimæric spleens from 3–10-day-old *A* strain mice (obtained by injecting spleen cells from adult *CBA* mice into *A* neonates), using a concentration of 15×10^6 cells per ml., it was possible to prepare 5–10 slides from each spleen and 100 or more clearly countable mitoses were usually present on each slide. This represented 20–30 per cent of nuclei in which chromosomes were visible. Ninety-four per cent of countable cells had the modal number of chromosomes.

In the technique described by Moorhead *et al.*[6], the final suspending medium before spreading was the fixative. It was found that the fragility of the nuclei could be [illegible]creased by using 45 per cent acetic acid, and [illegible] by 60 per cent acetic acid. Although it w[illegible]irable to leave the cells in the 45 per cen[illegible]rolonged period of time (usually ov[illegible]th the 60 per cent acetic acid fo[illegible] avoided, otherwise excessive s[illegible]f the chromosomes occurred a[illegible]. The thin film of frozen c[illegible] produced by cooling the slide with dry ice afforded good spreading, and immediately afterwards, adherence of the cells to the glass surface. Subsequent heating was important to complete the spreading of more resistant nuclei during drying.

We are grateful to Prof. M. F. A. Woodruff for his encouragement and advice, and to Dr. Donald Michie for his helpful criticism. One of us (M. F.)

Culture of Human White Cells using Differential Leucocyte Separation

SEVERAL variations of white blood cell culture methods for the purpose of human chromosome study are now in use. All these are derived from the method of Hungerford *et al.*[1]. We have used the original and some of the modified procedures, particularly that of O. J. Miller (personal communication). In our experience with these techniques, about 75 per cent of cultures produce adequate numbers of mitotic figures for examination, while the remaining 25 per cent grow poorly, if at all. It was our impression that most failures occurred in specimens containing large numbers of polymorphonuclear leucocytes. On incubation, such cultures became excessively acid, and large clumps of degenerating polymorphs appeared.

While visiting the laboratory of K.-E. Fichtelius at the Histological Institute in Uppsala in 1957, one of us (K. H.) observed a method for removing polymorphonuclear leucocytes from white cell suspensions. The method was used for a metabolic examination of lymphocytes (Fichtelius, K.-E., and Hallander, H., personal communication). The procedure utilizes the phagocytic properties of polymorphonuclear cells by permitting them to ingest iron particles. The iron and the cells containing it are then removed by a magnet. Similar methods for different purposes have been used by several other investigators[2–4].

We have incorporated this procedure into our culture method, and have since performed more than 150 consecutive cultures with absence of growth in only one case. Our present technique produces good mitotic-rates (Fig. 1) and well-spread metaphase plates suitable for analysis (Fig. 2). The procedure is as follows.

Draw 10–20 c.c. of venous blood into a heparinized syringe and transfer to a sterile tube. Place the tube in an incubator at 37° at a 45° angle for [redacted] min., until the red cells sediment. Transfer to a sterile container having a flat su te with two volumes of culture m 99 with antibiotics). Add appr of very fine sterile iron powde r at 37° C. for 30–60 min. f container down. The sha 100 strokes per minute. strong magnet for 5 min., transfer the supernatant to a sterile tube, and place this tube on the magnet for an additional 5 min. Transfer the supernatant to culture vessels. After performing a cell count, dilute the cell suspension with culture medium to achieve a final concentration of 0·5–1·0 × 10^6 cells per ml. (These are now 95–99 per cent mononuclear cells.)

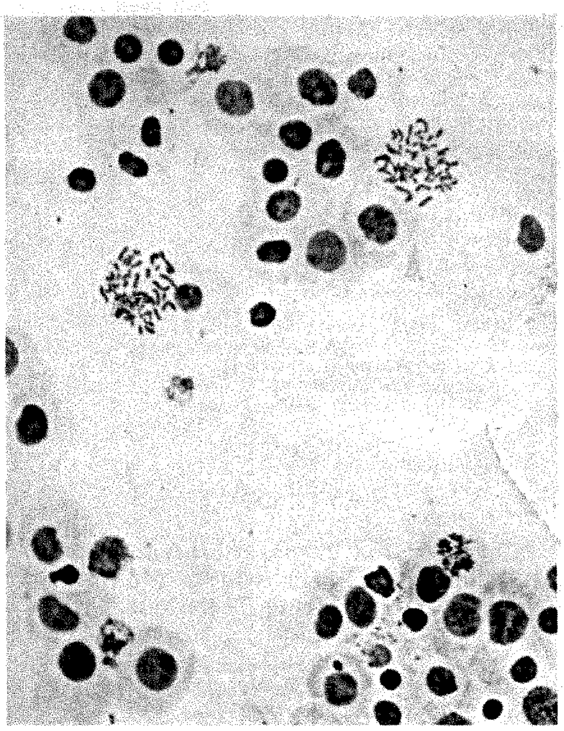

Fig. 1. Low-power view of growing mononuclear cells, showing mitotic figures swollen with hypotonic salt solution. Note nuclei of mononuclear cells in various stages of growth

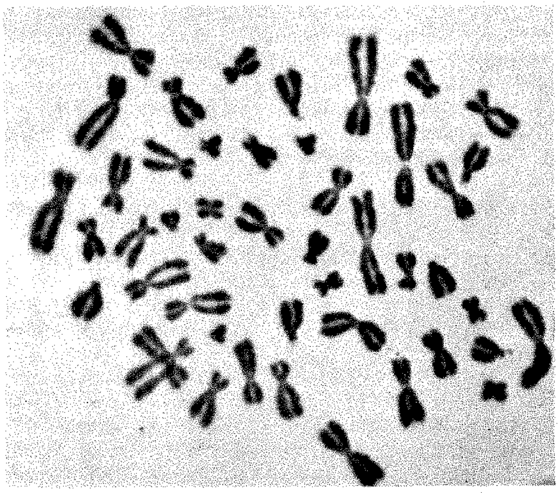

Fig. 2. High-power view of well-spread metaphase plate, showing chromosomes adequate for karyotype analysis

Add 0·2 ml. phytohæmagglutinin (Difco, type *M*) per 10 ml. of culture fluid and incubate at 37° C. for at least 72 hr. Add 0·1 ml. of 10^{-6} molar colchicine per 10 ml. of culture fluid. Incubate for an additional 2 hr. Examine a sterile sample of the culture under the phase microscope at this time. Particular attention is paid to clusters of mononuclear cells, which are examined for the presence of mitotic figures. If none is seen, incubate for an additional hour and repeat examination. When mitotic activity is observed, shake cultures well and centrifuge at 400 r.p.m. for 5 min. Suspend the cells in 1 per cent sodium citrate for 4 min. Add 1 drop of fixative (3 : 1 absolute ethyl alcohol–glacial acetic acid) and centrifuge at 200 r.p.m. for 2 min. Discard the supernatant. To the residue add the fixative very slowly with constant agitation to a volume of 1 ml. After 5 min., centrifuge at 400 r.p.m. for 5 min., resuspend in fresh fixative. (This may be repeated several times to improve chromosome spreading.) Place small droplets on a coverslip and air-dry by blowing. When dry, invert coverslip into a drop of 2 per cent acetic orcein on a slide and blot off excess stain for temporary preparation. For permanent preparations, immerse air-dried coverslips in stain for 1 min., dehydrate (tertiary butyl alcohol, 10 sec., twice; 1 : 1 tertiary butyl alcohol–xylene, 1 min.; xylene, 1 min., twice) and mount in 'Permount' or balsam. Such preparations are best examined by phase contrast. For bright-field examination, longer staining is required.

The technique outlined above depends for its success on the presence of a small amount of the substance phytohæmagglutinin, which appears to act as a mitotic stimulant[5]. Examination of growing cultures reveals that the mononuclear cells form large clusters, apparently as a result of the action of the phytohæmagglutinin, and it is only within these clusters that mitoses are found. That human mononuclear cells can be cultured *in vitro* without addition of phytohæmagglutinin is shown by the work of Timofejewsky in 1928 [6], where leucocytes from the buffy coat of centrifuged blood were grown in a plasma clot using autologous plasma. This suggests that part of the effectiveness of phytohæmagglutinin in causing leucocyte growth may be due to its ability to cause white cell clumping, providing an environment similar to that in a plasma clot.

This work was aided by grants from the American Heart Association, the U.S. Public Health Service (*H*–2202) and the New York City Health Research Council (*U*–1030).

Two Types of Ribonucleoprotein in the Nucleolus of Intestinal Carcinoma of the Newt following Injection of Herring-Sperm Deoxyribonucleic Acid

RECENTLY I demonstrated two types of ribonucleoprotein in the nucleolus of tumour cells in the squamous-cell carcinoma of the lizard *Lacerta agilis*[1]. To establish whether a more general significance should be attached to this result I performed a corresponding investigation with the experimental carcinoma of the intestine of the newt *Triturus alpestris* following injection of herring-sperm deoxyribonucleic acid (eight days injection with 0.1 ml. of 5 per cent solution)[2]. After killing the animals on the 40th day of the experiment the nucleolar differentiation of the tumour cells was studied by the toluidine blue-molybdate method[3,4]. As in *Lacerta*[1], the ribonucleoprotein of the nuclear sap or parachromatin was coloured deep purple, the nucleolus partly assuming a green colour. Also in *Triturus* the existence of two types of ribonucleoprotein, if not actually demonstrated, had thus become highly probable. In the nucleoli a variable quantity of metachromatic ribonucleoprotein, as well as a number of very small vacuoles, appeared to be present, remaining unstained by the method described here. In the interphase cells the metachromatic ribonucleoprotein was most distinct, being in the form of small granules, hollow spheres or clusters of hollow spheres. Examination with a phase-contrast microscope showed that the nucleoli of the living tumour cells contained numerous very small vacuoles.

Comparing the nucleolus in the toluidine blue-molybdate stained sections with that in the living tumour cell it could be ascertained that the metachromatic ribonucleoprotein was situated around, or in, some very small vacuoles. After pre-treatment with ribonuclease or hot trichloroacetic acid[5] this nucleolar ribonucleoprotein was not coloured. In all phases of staining by the toluidine blue-molybdate method staining could be obtained in the same way as the nuclear parachromatin. Following Love and Bharadwaj[3,4] it can, therefore, in this intestinal tumour of *Triturus* also be called the nucleolar parachromatin. Just as in the squamous-cell carcinoma of the lizard and the Ehrlich ascites tumour[4], the tumour cells in *Triturus* often persisted throughout the mitosis, without being incorporated in the daughter nucleus. During mitosis the nucleolar parachromatin exhibited a different localization: in early prophase it was frequently situated at the rim of the nucleolus, to disappear from view during the later prophase, and become clearly visible again in the metaphase, anaphase and telophase as a vacuolated nucleolus green-coloured in the toluidine blue-molybdate sections.

Love[3] suggested that the nucleolar parachromatin is probably extruded from the nucleolus during the prophase to contribute to the accumulation of the granular parachromatin, which takes place in this period. The results obtained for the *Triturus* tumour may certainly be an argument for this reasoning. The earliest symptom of reformation of the nucleolus in the daughter nucleus was a metachromatic inclusion, afterwards acquiring an outer coating of ribonucleoprotein staining green in the toluidine blue-molybdate sections, which could be vacuolated as well as amorphous. This nucleolar differentiation of the tumour cells in *Triturus* is undoubtedly related to the special structures known for a long time already in the nucleolus.

The relationship of the two types of ribonucleoprotein in the nucleolus to the nucleolini[6-8] and the nucleonemata[8] could also be solved with the data obtained from the intestinal tumour of *Triturus*. Also in the tumour cells of *Triturus*, hollow and solid structures, resembling the true nucleolini, could be demonstrated after staining with iron hæmatoxylin. The physiochemical differences in ribonucleoprotein determining the differential staining by the toluidine blue-molybdate method may, therefore, also be responsible for some differences in the affinity for the hæmatoxylin. As these results are in good agreement with those obtained in the Ehrlich ascites tumour cells[4] and the squamous-cell carcinoma of *Lacerta*, it would seem that they are certainly of general importance.

PSYCHIATRY

Erythrocyte Cholinesterase-levels in Mental Patients

RUBIN has published data[1a] on erythrocyte acetylcholinesterase which showed a bimodal distribution of this enzyme in schizophrenic patients This paper was criticized[1b] and the criticism answered[1c] Our work was an attempt to repeat Rubin's findings in larger groups of patients and normals

The assay procedure we used is based on the following reactions.

acetylthiocholine + erythrocyte acetylcholinesterase → acetate + thiocholine

thiocholine + dithiobisnitrobenzoate → yellow colour

The rate of formation of the yellow anion of 2-nitro-5-thiobenzoic acid is proportional to the enzyme activity This method is rapid and uses small amounts of blood (10 µl) and is useful for surveys of this type The plasma esterase was inhibited by addition of quinidine sulphate to the reaction mixture[3] The assays reported in this communication are therefore of the erythrocyte esterase Details of this method have been published[2]

Blood samples for the patient group were collected by the clinical laboratory staff from each patient on admission to this Institute At that time the patient's record number and the date of the blood withdrawal were noted A portion of the blood sample was assayed in our laboratories for erythrocyte acetylcholinesterase At the time the assay was performed, the clinical diagnosis was unknown to us After we had determined the erythrocyte acetylcholinesterase-levels of 64 patients, the diagnosis and status of these patients were studied A psychiatrist (E C) examined all the hospital records on members of this group The patients were then placed in the categories listed in Table 1 on the basis of the diagnosis recorded in the hospital record, supplemented by first-hand examination of the patients' chart The results we obtained are shown in Table 1

Table 1 ERYTHROCYTE ACETYLCHOLINESTERASE-LEVELS

Type	$\bar{x}$	σ	n
Normal *A*	1 08	0 18	75
Normal *B*	1 01	0 16	8
Schizophrenic, no drugs	0 98	0 12	16
Schizophrenic, on phenothiazine	1 02	0 22	6
Organic psychoses and epilepsies	0 98	0 42	11
Psychoneuroses	1 00	0 23	13
Depressions	1 12	0 15	10

$\bar{x}$, Observed mean-rate (moles substrate hydrolysed per min. per red blood cell × 10^{15})

σ, Standard deviation of the group

n, No. in each group

The group labelled Normal *A* is a sample of individuals who volunteered finger-tip blood during a display of medical research facilities held on this campus The equipment for assaying the erythrocyte acetylcholinesterase was on display and the assays were performed in public Persons whose blood was taken by our clinical laboratory and who were not patients (for example, physicians, nurses, staff, students, etc) are included in the classification Normal *B*

The results indicate that we cannot distinguish hospitalized mental patients from non-hospitalized, presumably normal persons, on the basis of mean erythrocyte acetylcholinesterase rates The group called 'psychoses and epilepsies' did show considerably greater variability than the other groups For this reason, we decided to follow the erythrocyte acetylcholinesterase rates for several days in these patients, to see if this difference was significant

In summary, an epileptic patient was hospitalized for more than a month During that period 28 erythrocyte acetylcholinesterase determinations were performed on his blood cells Some of these were shortly prior to, others shortly after, seizures; some were quite distant in time before or after seizures. In addition, on two occasions we were able to make determinations at regular intervals after a seizure In no case was there any obvious correlation of the duration or time of occurrence of the seizure with the observed erythrocyte acetylcholinesterase-level. Nor were his rates different from the normal (1 09 ± 0·12, Table 1) for the whole series In a smaller series from two other such patients similar negative findings were observed We believe, therefore, that the original observed large variability in this group of patients was an artefact of the small sample.

In re-examining Rubin's results it is clear that the major difference between his results and ours is the magnitude of the standard deviations observed. Our normals show about 15 per cent variation from the mean value In a series of 101 human adult subjects, Sabine[4] showed a standard deviation of 10 per cent about her mean value Sawitsky[5] reports a standard deviation of a group of 15 normal subjects which is 9 6 per cent of their mean activity Rubin, on the other hand, observed a 3 per cent variation Had his variation been as large as 10 per cent, his results would have been similar to ours

The number of verifiable physiological differences between mentally ill patients and normals is small and any new observations in this field would be of value in assessing the etiology and progress of the disease The difficulties of confirming the results of one investigation by another investigator in the field of mental health has been discussed by Kety[6] We have been unable to confirm Rubin's results

We wish to acknowledge the help and co-operation of Dr Robert B Anderson, Department of Neurology, University of California Medical Center

FORTHCOMING EVENTS

Thursday, December 28

Royal Institution (at 21 Albemarle Street, London, W 1), at 3 p m —Sir Lawrence Bragg, F R S "Electricity" The One Hundred and Thirty-second Course of six lectures adapted to a Juvenile Auditory. Further lectures on December 30, January 2, 4, 6 and 9)

Thursday, December 28—Friday, December 29

World University Service (at B M A House, Tavistock Square, London, W C 1), at 10 30 a m on Thursday and 10 a m on Friday—Conference on "The Student and Mental Health"

Friday, December 29

Royal Society of Arts (at John Adam Street, Adelphi, London, W C 2), at 2 30 p m —Dr A D Booth "Machines that Think" (Mann Lecture)

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Physicist (preferably with experience in isotope techniques, including autoradiography and physical methods for microanalysis) in the Department of Preventive Dentistry, to engage in research into the mechanism of the action of fluorides in preventing dental caries, in co-operation with a research team including chemists and dental pathologists and histologists—Prof J L Hardwick, Turner Dental School, The University, Manchester 13 (December 28).

Librarian—The Secretary, University of East Anglia, City Hall, Norwich, Norfolk (December 30)

Junior Lecturer (interested in stratigraphy and sedimentation) in Geology—The Registrar, Trinity College, Dublin, Republic of Ireland (January 1)

Lecturer or Assistant Lecturer (medically or non-medically qualified) in the Department of Histology—The Registrar, The University, Liverpool, quoting Ref No CV/5/2/N (January 1)

Lecturer in Applied Mathematics, to take charge of the Electronic Computation Laboratory—The Registrar, University College, Singleton Park, Swansea (January 5)

Lecturer (medically qualified, and with special experience in histopathology) in Pathology—The Registrar, Trinity College, Dublin, Republic of Ireland (January 15)

Lecturer in Geology (Mineralogy and Petrology) at the University of New England, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, January 15)

Lecturer in Microbiology in the Department of Agriculture, University of Sydney—The Secretary Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, January 19)

Senior Lecturers (2) in Anatomy at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, January 19)

Assistant Lecturer in Botany—The Registrar, The University, Manchester 13 (January 20)

Senior Lecturer/Lecturer in Bacteriology at the University College, Ibadan, Nigeria—The Secretary, Senate Committee on Colleges Overseas in Special Relation, University of London, Senate House, London, W C 1 (January 22)

Senior Lecturers or Lecturers (with at least an honours degree or equivalent qualifications, with experience and research interests in pure mathematics) in Mathematics at the University of New South Wales—The Agent-General for New South Wales, 56–57 Strand, London, W C 2, and The Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, N S W , Australia (January 26)

Lecturer in Engineering, for duties which will include teaching and research in applied mechanics and one or more of the usual civil engineering subjects—The Secretary, The University, Aberdeen (January 31)

Lecturer in Physics—The Registrar, The University, Hull (January 31)

Reader in Physics at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office,) Marlborough House, Pall Mall, London, S W 1 (Australia and London, January 31)

Research Fellows (2) in Hydrobiology, to work on fundamental problems in Lake Kariba at the Nuffield Kariba Research Station (University College of Rhodesia and Nyasaland)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (January 31)

Lecturer (with special qualifications or experience in inorganic chemistry or in some branch bearing on inorganic chemistry) in Chemistry at the University of Canterbury—The Registrar, University of Canterbury, P O Box 1471, Christchurch, New Zealand (February 28)

Robert Blair Fellowship in Applied Science and Technology tenable for one year of advanced study or research abroad—The Education Officer (WA 14/N/3316/12), County Hall, London, S E 1 (March 12)

Assistant Biochemist, Basic grade (preferably holding the A R I C , the Grad Mem R I C or B Sc (Hons) in chemistry), in the Group Laboratory at Crumpsall Hospital—The Hospital Administrator, Crumpsall Hospital, Manchester 8

Assistant Experimental Officer (with a pass degree, H N C , or equivalent, or, if under 22, G C E "A" level, O N C or equivalent) in the Chemistry Department, to help with research on the forms of combinations of magnesium, calcium and phosphate in cattle diets and ingesta, and on the development of the analytical methods used —The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, quoting Ref 61/15

Assistant Experimental Officer (with a pass degree, H N C or equivalent, or, if under 22, G C E "A" level, I N C or equivalent) in the Physics Department, for work on the flow and coagulation of blood—The Secretary, National Institute for Research in Dairying (University of Reading, Shinfield, Reading, quoting Ref 61/19

British Petroleum Research Student (with experience in microbiological techniques) in the Department of Chemical Engineering, for research on the conversion of petroleum hydrocarbons into fatty acids—The Secretary, University College London, Gower Street, London, W C 1

Graduate Assistants in Biochemistry—Dean, Faculty of Graduate Studies, University of Alberta, Edmonton, Alberta, Canada

Head of the Science Department, Head of the Mathematics Department, and Assistant Masters to teach Science, Mathematics and Biology—The Secretary, Atlantic College (U.K), Ltd , Denmark House, 71/72 Piccadilly, London, W 1

Physicist, for teaching and fundamental research—Head of the Department of Physics, Victoria College, Victoria, B C , Canada

Physics Laboratory Technician (man or woman, with experience of work in a teaching laboratory)—The Secretary, Royal Holloway College, Englefield Green, Surrey

Principal Lecturer in Cloth Manufacture and Applied Testing, a Senior Lecturer in Textile Physics, with particular emphasis on the structure of natural and man-made fibres, a Senior Lecturer in General Textiles and Testing Methods, a Senior Lecturer in Design and Colour, a Lecturer (physicist or mathematician) for statistical work in textile engineering, and a Lecturer in Physical Chemistry, for the application of chemistry in textile processing—The Registrar, Bradford Institute of Technology, Bradford 7

Principal Veterinary Research Officer (member of the Royal College of Veterinary Surgeons, or with an equivalent qualification) with the Federal Government of Nigeria—The Recruitment Attaché, Nigeria High Commission, 9 Northumberland Avenue, London, W C 2, quoting Ref Z 5/3

Senior Lecturer in Automatic Control in the Department of Production Technology and Control Engineering—The Secretary, Northampton College of Advanced Technology, St John Street, London, E C 1

Specialist Officer (Plant Nematologist) (with a first- or second-class honours degree in natural science (botany or zoology) plus two years postgraduate experience) with the Federal Government of Nigeria—The Recruitment Attaché, Nigeria High Commission, 9 Northumberland Avenue, London, W C 2 quoting Ref B 16/2

POLITICS AND EDUCATION IN GHANA

RECENTLY, three Cabinet Ministers of Ghana—Mr. Adamafio, Minister of Information and Broadcasting, Mr Duwuona-Hammond, Minister of Education, and Mr Boateng, Minister of the Interior—have issued warnings to the students of Ghana's two Universities concerning their "arrogance and anti-State activities" which, so the Ministers declare, have been inherited "from a colonial past". We believe that anyone, student or otherwise, who indulges in serious anti-State activities should be warned and, if necessary, punished; but there is all the difference between anti-State activity and open opposition to the political policy of those in power—at any rate in a democracy Moreover, to accuse the students, or anyone else, of arrogance strikes one as being somewhat naive—even childish

Recently, Osagyefo Dr Kwame Nkrumah, President of the State of Ghana, was installed as Chancellor of the University of Ghana, near Accra, and on November 29 he was also installed as Chancellor of the Kwame Nkrumah University of Science and Technology at Kumasi We understand there was an obvious lack of enthusiasm among the students during both these ceremonies, which angered the President Though one cannot conceive of such resentment being demonstrated in such countries as the United States or Great Britain, the President's annoyance can be readily understood, though to appoint one and the same man as Chancellor of the only two Universities in a country is unique and risky, and in this case the objective seems very clear, it bodes ill for any semblance of autonomy in either University

Wearing of academic gowns has been banned, and apparently stern measures, including the dismissal of some lecturers known to be "instilling in their students an attitude of disrespect for the President", are to be taken The first policy strikes one as being absurd, and seems to be aimed against any attempt to follow the custom of many universities in the more highly developed countries The second decision is more serious Students are notoriously interested in politics, and are surely old enough to think for themselves, which is the very basis of a university education. It is a student's responsibility to think, but if as a result of such thinking he threatens to be a bad citizen, then he should be dealt with accordingly by his immediate superiors, that is, the university authorities and not those outside the university who enjoy political power

All three Ministers have threatened that any students who "misbehave would be thrown out". This warning, too, should come from the university authorities and not from the State This appears to be an intolerable position for any university, for it seems that those responsible for the running and development of the university are to be deprived of an important part of their academic responsibility. It should be they, and only they, who should take to task their students for breaches of university discipline (including, if necessary, expulsion) and not any outsider, not even a Minister of State

The Minister of Information and Broadcasting in Ghana has announced that from now on the Council of the University of Science and Technology will be directed by the Government in the running of that institution so that the Government "might turn out men and women who have unflinching loyalty to the office and person of President Nkrumah". If this is to be taken literally, it savours too much of undesirable dictatorship This alarming statement implies at least three conditions (1) appointments to the staff must meet with the approval of the Government in power, (2) entry of students to that University will be conditional on (among other things) political grounds, (3) the University staff and their authority and the students will be subject to the whims and fancies of the Government

There can be no autonomy in such an institution, no freedom of thought, expression and action, no development of democratic ideals In fact, if the threats and warnings made by certain Ministers of State in Ghana are carried out, the University of Ghana, and certainly the University of Science and Technology, will not be universities at all

On December 4, Mr Duwuona-Hammond, the Minister of Education, addressed three hundred Ghana school teachers and told them that they must show loyalty to "the ideals of the State and of its chief architect, President Nkrumah" He proceeded to say "Nobody resents fair comment, but systematic, spiteful and irresponsible criticism calculated to undermine the Government cannot be accepted as sincere teaching" The second statement would be acceptable to all educationists, but it will be understandable, in view of the first statement, if they suspect why it was made

Ghana is an emergent country It has fairly and justifiably won its independence But it has yet much to learn, and during the past few decades the University of Ghana has been learning and developing with the help of academic men and women from the world's older universities—especially those of Great Britain In Britain, the universities are proud of their autonomy and guard it with justifiable jealousy, though, in spite of the fact that they are increasingly dependent on State funds, they suffer no threat of State interference in the way they are conducted and the manner in which they train their students. Moreover, much to their credit, successive Governments have shown no tendency to influence the universities so far as policy is concerned In fact, university students are encouraged to think for themselves, and, within reason, are entitled to their own political views and to express their opinions of Government and others in political power. Ghana would be wise to take note of this

ELECTRON MICROSCOPY

Proceedings of the European Regional Conference on Electron Microscopy

Delft, 1960 Edited by A L Houwink and B J Spit Vol 1 Pp i–xvi + 1–608 Vol 2 Pp xvii–xxvii + 609–1075 (Delft· Nederlandse Vereniging voor Electronenmicroscopie, 1961) 135 florins the two volumes

It is very appropriate that the 1960 Regional Conference on Electron Microscopy should have been held at Delft, as was the first Conference in 1949 Delft is in a very real sense the birthplace of microscopy, and it is a fitting tribute to Antony von Leeuwenhoek, possibly the most acute of all microscopists, and a happy gesture that the covers of these two volumes should be impressed with an image of one of his microscopes The twelve years which have elapsed since the first Conference have witnessed spectacular advances in this newer form of microscopy, both in technique and in the number of workers using the instrument It could scarcely have been imagined, for example, that stemming from the first ultra-thin section demonstrated at Delft by Brettschneider in 1949, the use of sectioning for electron microscopy would by 1960 have become so routine a matter as to be in regular use in a multitude of electron microscope laboratories Indeed, what impresses the reader of these volumes the most is both the range of materials which can be examined by this means and the extremely rapid, even explosive, burst of interest developed during these few years

The books comprise reports of 246 articles presented at the Conference, copiously illustrated by electron micrographs They are not therefore intended to be read, in the sense that text-books are read, but rather to be used as works of reference The first volume, containing 138 articles, deals in the main with instrumentation, including an article on specimen techniques, with crystal physics and with metallurgical and other industrial applications The second, of 108 articles, is devoted exclusively to biology The leading article in Volume 1 deals with electron optics, leading naturally to a discussion of developments both in electron microscopes and in methods of use The articles on solid-state physics (including crystal growth and lattice defects) are perhaps especially notable In Volume 2 the cytology of muscle, skin, bone, sense organs, spermatozoids, and viruses all receive due attention It is somewhat disappointing to see that while animal cytology is represented by a hundred articles, plant cytology accounts for only eight

These two books together cover much of the field as explored in 1960 Even a cursory glance through the list of contents, however, reveals the absence of some names already famous in the field of electron microscopy and some lines of research, both well established and developing, which are not represented This is clearly a fault neither of the organizers of the Conference nor of the editors, and explanation is surely to be sought on other and more fundamental lines One contributory factor is that conferences on electron microscopy by their very nature meet only part of the needs of electron microscopists Few workers are specifically interested in the instrument itself or even in their own electron micrographs alone Rather are they interested in the results of electron microscopy as illuminating their own chosen fields and as contributing to the solution of problems often already stated before the advent of this new technique and of interest also to non-microscopists They therefore both receive and confer more benefit by discussions in conferences arranged by their own professional bodies, before audiences acquainted with and sympathetic to their problems, than by reports to those with whom the only interest in common is the instrument itself While it is clearly satisfactory to electron microscopists that they should form societies, and hold symposia which attract large numbers of articles, and while it is clearly desirable that electron microscopists should meet from time to time, it is not self-evident that the best interests of the separate sciences are achieved in this way

The books are beautifully produced on excellent paper and the illustrations could in most cases scarcely have been better Bibliographies are attached to each article, and each volume carries a complete author index Both the publishers and the editors are to be complimented on this work It is notable, moreover, that in these days of publication delays, the books have appeared in less than one year from the date of the Conference, it is not easy to see how this herculean task has been performed and the editors are to be highly commended on it

Anyone who wishes to acquaint himself with the situation in electron microscopy up to 1960 could do no better than to read these two volumes.

R D Preston

FLORA OF THE ZAMBEZI BASIN

Flora Zambesiaca

Mozambique, Federation of Rhodesia and Nyasaland, Bechuanaland Protectorate, Vol 1, Part 2 Edited by A W Exell and H Wild Pp vi + 337–581 (London Crown Agents for Oversea Governments and Administrations, 1961 Published on behalf of the Governments of Portugal, The Federation of Rhodesia and Nyasaland, and the United Kingdom) 25s

The second part of the first volume of *Flora Zambesiaca* has made its welcome appearance The part completes Volume 1, for which an index and title-page are provided It covers the flowering plants from family 21, Caryophyllaceae to family 30, Sterculiaceae arranged in the Bentham and Hooker sequence The joint editors are Mr A W Exell of the British Museum (Natural History) and Dr H Wild of the Federal Herbarium, Salisbury, Southern Rhodesia This part, as in the case of the first part, is an excellent example of botanical co-operation, for it contains contributions by botanists working at the British Museum (Natural History), the Federal Herbarium, Salisbury, Southern Rhodesia, the Botanical Laboratory of the Free University, Brussels, the National Herbarium, Pretoria, and the Royal Botanic Gardens, Kew, while the Portuguese Government is represented both on the Managing Committee and the editorial board of this Flora The Flora covers the Federation of Rhodesia and Nyasaland, Mozambique and Bechuanaland Protectorate The part under review contains accounts of 10 families, consisting of 55 genera and 265 species The largest family is the Malvaceae with 16 genera and 111 species in the area while the smallest is the Theaceae with one monotypic genus *Ficalhoa*, alone The plants included range from small annual herbs with inconspicuous flowers such as *Bergia* (in the Elatinaceae) to large forest trees, 30 m high, such as *Sterculia subviolacea* (in the Sterculiaceae), and the massive baobab, known scientifically as *Adansonia digitata* (in the Bombacaceae), so familiar to travellers in the drier parts of eastern and southern Africa.

The diagnostic keys, provided to distinguish the genera, species and in some cases the varieties, show signs of having been carefully prepared, and should be of great assistance to the user. The 46 plates, drawn by eight different artists, are of a high standard and add greatly to the helpfulness of the book, while the coloured frontispiece, depicting *Hibiscus rhodanthus*, is a pleasing addition.

The treatments adopted are in some cases interesting. The Hypericaceae merged with the tropical family Guttiferae will surprise botanists familiar with the temperate genus *Hypericum* alone. The placing of *Ficalhoa* in the Theaceae is now rather widely supported, as one has long felt unhappy about its being in the Ericaceae. The acceptance of the Illecebraceae as a family distinct from Caryophyllaceae shows how much the personal opinions of botanists enter into taxonomic decisions. Only recently, in another African regional Flora, these two families were treated as one.

At the generic level, *Hibiscus esculentus*, the young fruits of which are the well-known tropical vegetable okra, is placed in the genus *Abelmoschus*, while the tree widely spread throughout the area and hitherto known as *Thespesia garckeana* finds itself in the unfamiliar genus *Azanza*.

When one comes to species, one finds that a more conservative view has been taken, and a number of familiar names appear in synonymy. This tendency to accept a broader view of a species is very welcome and can at least partly be attributed to the taxonomists knowing the plants in the field and learning at first hand how greatly climatic, seasonal and edaphic conditions can modify them. It will undoubtedly make the Flora easier for the public to use.

The production is excellent, and the authors and editors are to be congratulated on the high standard of this much-needed work.

E. MILNE-REDHEAD

A BOTANICAL PANOPTICON

A New Illustrated British Flora

By Dr. Roger W. Butcher. Part 1: Lycopodiaceae to Salicaceae. Pp. viii + 1016. (London: Leonard Hill (Books), Ltd., 1961.) 84s. net.

THERE was a time when every aspiring student of British plants first groped his way through "Bentham and Hooker" and then, with growing confidence, broached the more esoteric contents of "Butcher and Strudwick". The fact that it was generally considered unnecessary to mention the precise titles of either work was proof not only of the general popularity of the *Handbook of the British Flora* and *Further Illustrations of British Plants*, but also of the almost legendary fame of their respective authors. Dr. Butcher showed keen psychological insight in naming his book *Further Illustrations*, for, to be quite honest, most beginners and amateurs valued pictures more highly than text, and many professional botanists, now ageing and erudite, would, under pressure, confess that it was the genius of Walter Fitch and the urbane lucidity of Florence Strudwick, rather than the arid exactitudes of botanical prose that guided their first steps along the rocky road of taxonomy.

Is the same true nowadays? Do young naturalists still turn to Fitch and Strudwick for assistance? Or has modern youth inherited such bumps of scientific understanding that it can imbibe Clapham, Tutin and Warburg as mother's milk and advance to erudition via chromosomes and histograms? I do not think so—nor evidently does Dr. Butcher—for his *New Illustrated British Flora* differs in no material respect from his earlier book on British plants. It is *Further Illustrations* expanded to include the entire range of native British phanerogams and vascular cryptogams, as well as many of the more widely established colonists, denizens and aliens. Almost the only concession to the 'new look' in British botany is the departure from the Bentham and Hooker sequence of families in favour of the Clapham, Tutin and Warburg scheme, and even here Dr. Butcher accepts the latest of phylogenetic vagaries with such ill-concealed reluctance that one wonders what irresistible forces compelled him to take this course.

The sad fact that Florence Strudwick did not live to prepare the illustrations for this new work has resulted in a loss of uniformity in the style and quality of the illustrations, though it should be added that at least two of the ten artists employed have attained Miss Strudwick's immaculate clarity and firmness of line, and that, on the whole, the 885 drawings in this first volume are perfectly satisfactory. The same, alas, cannot be said for the reproduction, perhaps in the case of those drawings transferred from *Further Illustrations* because the blocks have deteriorated with age, but less easily explained in other cases. Too many of the illustrations, at least in the review copy, are unduly black and murky, while a few are pallid to the point of anæmia. Something has surely gone wrong with *Equisetum hyemale* (Fig. 10) which, to judge from the scale, appears to be more slender than *E. trachyodon* (Fig. 11)—or should the illustrations be interchanged? The flowers of *Barbarea vulgaris* (Fig. 209) also appear considerably larger than those of *B. verna* (Fig. 212), which is neither in accordance with the facts nor with the accompanying legends.

Such minor slips and blemishes are, however, virtually inevitable in a detailed work of this magnitude. It is more general matters, such as the author's choice of subjects for inclusion in the volume, that are likely to intrigue the critics. Of course one recognizes the futility of wasting space on every fleeting casual and rubbish-tip waif that postures as a British plant, but it is difficult to follow the logic which admits *Hypericum canadense* and excludes *Cerastium brachypetalum*, which allows *Viola kitaibeliana* and disallows *Ranunculus muricatus*, and when one comes to scrutinize the so-called 'critical groups', even the most sanguine must begin to despair. Are there really ten species of *Thalictrum* in Britain—or for that matter six (or seven) *Cochlearias*? It would be unfair to expect Dr. Butcher to solve, at one blow, all the problems which have overtaxed the mental equipment of generations of taxonomists, but one cannot help feeling that if these, and a hundred similar problems in *Juniperus, Caltha, Erophila, Arabis, Viola, Polygala, Sagina, Salicornia*, etc., were to be given serious attention, not by one botanist, but by a group of botanists, prepared to follow up every possible clue, then elucidation would follow. Perhaps not, for it may be that our whole system of taxonomy and nomenclature is too crude and static to encompass the restless mutatings of living things, but at least the effort would be praiseworthy. Besides, it is demoralizing for any scientist to have to keep on repeating what he does not wholly believe.

It is sad to find that Dr. Butcher has joined forces with those who require a popular name for every unpopular plant: one senses political undertones in 'Red German Catchfly' (*Lychnis viscaria*), redressed perhaps by the fact that *Rumex orientalis* has escaped to become the 'Western Dock' and—it was bound to happen sooner or later—one blushes at the frankly clinical implications of Dickie's Bladder Fern. How fortunate that *Cystopteris dickieana* is such a very rare plant!

Finally, it must be pointed out that the Achlamydeae, Group VI (p. 37) in the mammoth identification key, do not have "both calyx and corolla present".

R. D. Meikle

THE MITES AND TONGUE-WORMS OF AFRICAN VERTEBRATES

The Arthropod Parasites of Vertebrates in Africa South of the Sahara, (Ethiopian Region)

Vol. 1 (Chelicerata). Edited by F. Zumpt. (Publications of the South African Institute for Medical Research, No. 1, Vol. 9.) Pp. vi+457. (Johannesburg: South African Institute for Medical Research, 1961.) R. 6.00.

The "onlie begetter" of this handsome volume was undoubtedly the *Check List* of the late G. A. H. Bedford, published during 1927–36, a fact which is acknowledged in the first sentence of its introduction; it would perhaps have added a further touch of graciousness if it had been made clear that the very form of the present compilation is that inaugurated by Bedford—keys, figures, method of specific citation, sections, notes and even the general typography. Bedford's achievement was a great one, and to admit it to be so does not in the least diminish one's admiration for the extreme care and competence of all the authors of this, Bedford's successor.

Three decades of research in this field have increased the numerical total of Bedford's *Check List* many times and the present volume adds numerous new and excellent figures and completely new keys. The extreme care which has been taken by all the authors can be seen in the treatment of 'difficult' genera, for example, *Haemolaelaps*. A conservative systematics is evident everywhere, and if some acarologists feel that occasionally this conservative constraint may obscure some important relationships (as in some feather-mite genera), none, at least on the eastern side of the Atlantic, but will welcome the consequently rational treatment such as is accorded the Trombiculidae, in which family the fluidity of present-day generic concepts is frankly recognized and reflected.

The general introductory discussion of arthropod parasitism is succinct and reliable, and, within the obviously set limits which have been imposed, gives a useful survey of the subject for the purposes of the general student; but it leaves unanswered, of course, several problems such as why, for example, there are different patterns in the reduction of the biological cycle of the Acari. In this connexion it might be mentioned that the extremely complicated matter of the evolution of parasitism in the Trombidiformes is clearly if rapidly sketched, but one imagines that there will be several workers who will share my resistance to the suggestion that the Ereynetidae have evolved from "Trombicula-like" ancestors.

It seems ungrateful, given here so much, to ask more, but one could have wished for a system of cross-references between the bibliographical citations and the records. This would have made for easy validation of the latter, and although the specialist can perhaps often make an intelligent guess, the non-specialist has the labour of working systematically through all the entries. *Optat ephippia bos piger, optat arare caballus.*

FIFTY YEARS OF STEDMAN

Stedman's Medical Dictionary

Twentieth edition, completely revised. Pp. xlvii+1680+31 plates. (London: Baillière, Tindall and Cox, Ltd., 1961.) 110s.

Any published work which has run into its twentieth edition has proved its worth. In 1911, Thomas Lathrop Stedman compiled the first edition of his medical dictionary which, compared with the latest, was relatively so simple that he needed no collaborators.

When the present work was projected, a team of experts in the various phases of medical lexicography was brought together to act not as advisory consultants but as working partners. These twenty-three consulting editors include such names as Prof. A. I. Lansing, C. D. Leake, and N. B. Taylor, and are supported by outstanding colleagues in the fields of dentistry and pharmacology. Together they have scrutinized each entry in the nineteenth edition, re-defined many thousands of them and inserted a vast number of new ones. Each entry carries with it, if necessary, a reference to the appropriate anatomical or pharmacological nomenclature, while tables are used for many sorts of entries, for example, methods, operations, diseases, anatomical structures and pharmacological terms.

One difference between this and other medical dictionaries is that it carries many dental terms; the volume will be equally useful to dental practitioners and students as to members of the medical profession. Many entries also relate to veterinary science. Obsolete words and expressions, duplications and repetitions have been eliminated while terms relating to botany, homœopathy, eclectic medicine, life insurance and electricity are also omitted unless they have medical applications.

Such wholesale alteration has meant a resetting of the entire work. The publishers have consequently used a new type face and arrangement which make the entries much easier to find and read. The pages are larger and there are many more of them. Pronunciations are given only where the editors consider English-speaking readers might have difficulties. With the vastly improved illustrations, the high-quality paper and the sturdy binding, *Stedman's Medical Dictionary* in its twentieth edition is so new that it resembles the first one only in bearing the name of Stedman. Although prepared in the United States, the producers had all English-speaking readers in mind during the production and the dictionary can be recommended to all who read English as remarkable value for money.

K. M. Hawkins

Handbuch der Papierchromatographie

Herausgegeben von I M Hais und K Macek Band 2 Bibliographie und Anwendungen Pp xxiv+726 (Jena Gustav Fischer Verlag, 1960) 44 D M

IN their introduction, the editors state that as it was difficult to incorporate a comprehensive bibliography on paper chromatography in their first volume on principles and techniques, they decided to do this separately in a second volume This book contains more than 10,000 references (about four times as many as in Volume 1) and the arrangement follows roughly the same pattern as that of the subject-matter of the first volume. The references cover the period up to 1956, each is numbered and each title is given in full if the original language is English, French or German, otherwise the English or German translations as they occur in the recognized abstracts in these languages are given The literature is covered very thoroughly, and there is probably no publication of any importance or interest about fundamentals or applications which has been missed The systematic sectional arrangement, cross-references and comprehensive indexes of subjects and authors make for easy location of references to any desired topic in which paper chromatography has played a part

R CONSDEN

Précis de Climatologie

Par Prof Ch P Péguy Pp iv+348+3 planches (Paris Masson et Cie , 1961) Broché 42 N F , Cartonne toile 52 N F

THE studies on various aspects of physical geography and related sciences published since 1958 by Masson et Cie have gained wide acceptance as soundly based, timely and authoritative and the *Précis de Climatologie* maintains well the standards set by earlier volumes of the series Prof Péguy approaches his topic on a global scale, and is also actively concerned to demonstrate the practical applications of climate and weather to human and vegetal life His method is first to discuss the elementary physical principles involved in climate: atmospheric radiation and circulation, temperature, humidity, and air mass characteristics, then to show the interrelations of these elements both on a local scale and for Earth as a whole; and next, to consider the effects of these elements on soils, and plant and animal life (especially human) Lastly, present-day theories are reviewed with, on occasion, evaluation by the author of differing approaches to a particular problem—for example, by Sorre and Koppen in the matter of thermal zones

This treatment has the important advantage of subordinating theory and basic principles to interrelationships and effects within the natural environment, and thus Prof Péguy's study is useful not only for geographers but also for the agronomist, botanist, planner and engineer concerned with problems of land development Recent advances and trends within the subject can be treated at some length as a logical culmination frontal and air-mass analysis, evapo-transpiration, rainfall dispersion, intensity, and efficacy, and the concept of water-budgets There are also sections on climate classification and fluctuation

With such an approach there can, however, be considerable risk of over-simplification and superficiality, especially when allied to a concise, near-didactic style of presentation This the author in general avoids, due to extensive use of numerical examples, graphs, and a rigid statistical treatment of material Too often in climatological treatises there is an insufficient factual basis—this is by no means the case here although in one or two rare instances (for example, treatment of geostrophic forces and discussion of frontal surfaces) greater detail and clarity might have been attained One might also have expected more than four pages on micro- and local-climates, especially in view of the exhaustive discussion of such matters as angle of incidence of the solar beam

These, however, are very small matters when viewed alongside the many and solid merits of Prof Péguy's work Here in one volume we have a spread of modern climatological topics so far not brought together (at least in English), with a wide range of examples from the work of research workers both in Europe and America, completed in many instances by a review of future research possibilities The work is a distinct advance in the subject, and is a demonstration of geographical techniques applied soundly to scientific material

W B FISHER

Wunderwelt Kakteen

Von Curt Backeberg Pp 242 (176 Abbildungen) (Jena Gustav Fischer Verlag, 1961) 19 50 D M

THIS is one of the most entertaining books that the reviewer has read for a very long time Dr. Backeberg is possibly the world's foremost authority on the classification of the Cactaceae and has published six large volumes on the taxonomy of the numerous species, magnificently illustrated and containing a wealth of critical judgment But Dr Backeberg is not concerned with taxonomy in the book that lies before us Here we are introduced to the Cactaceae, not in the arid fashion of a botanical treatise, but most entertainingly to what he calls the "miracle world" of these extraordinary plants The first miracle is how they manage to exist in some of the most arid and inhospitable parts of the Earth The second miracle is the amazing variety of shape, size and characteristics developed A glance at the family members shows that in size the species vary from huge specimens of several tons weight to minute marble-size prickly spheres, in shape they may be cylindrical, spherical, erect, simple or branched, the surface may be smooth, wavy or furrowed, with or without a fearsome armament of spines, the flowers, whether large or small, night- or day-flowering, are, by any standards, beautiful, the flesh of some species yields food and drink, and the notorious drug mescalin can be obtained from another

Many additional uses are mentioned, one macabre, some utilitarian, some humorous The Aztecs slaughtered their human sacrifices on a bed made from the cut stems of one of the larger specimens The frame-work of a hut can be made from the stems of other species "Cactus fiends" in California decorate their clothing with cacti while "Miss Cactus" wears a spiny crown These prickly plants are a boon to the caricaturist, for the man who sat down on a cactus can scarcely fail to raise a smile Romanticists have even written poetry about them, and such is their attraction that "out and out" fiends will even descend to barefaced theft to acquire a rare specimen

The book is beautifully illustrated, beautifully printed, a credit to Dr Backeberg and, let us add, worthy of the Cactaceae

N L BOR

SMITHSON TENNANT, 1761-1815

By Dr. A. E. WALES
Principal, Burnley Municipal College

SMITHSON TENNANT was born at Selby, Yorkshire, on November 30, 1761, and christened in the Abbey Church there on December 3. His father, the Rev. Calvert Tennant, was the younger son of Edward Tennant of Mount Parke Farm, Wensley, and a Fellow of St. John's College, Cambridge. His mother was Mary, the only surviving daughter of William Daunt, apothecary of Selby. The Rev. Calvert Tennant's sister, Alice, married George Dinsdale of Nappa Hall, Wensleydale, and her daughter Alice married Christopher Pryme of Hull. The son of this marriage was George Pryme (1781–1868), who held the professorship of political economy at Cambridge, while Tennant was the professor of chemistry there (1813–15).

Tennant lost his father when he was ten years old, and his mother, by a fall from her horse while they were out riding in 1781, when he was twenty. During the intervening period, he attended the grammar schools of Scorton, Tadcaster and Beverley, in all of which he was fortunate to come under the influence of progressive and enlightened headmasters. It was during this period that the foundations of his later life as a natural philosopher were laid, for in addition to a good grounding in the classics, mathematics and French, the early interest in science which resulted from studying his grandfather Daunt's books was further encouraged by attendance in Tadcaster at the lecture of a Mr. Walker, an itinerant lecturer on popular science, and by the full use which he made of the excellent library at Beverley Grammar School, in which he found and eagerly studied a copy of Newton's *Treatise on Optics*.

His mother encouraged his growing love for science, and in 1781 plans were made for him to live as a pupil with Joseph Priestley. These, however, fell through and instead, just after his mother's fatal accident, Tennant entered the University of Edinburgh ostensibly as a medical student, but in reality so that he could study chemistry under Black. His notebooks of Black's lectures on chemistry, those of Munro Secundus on anatomy and surgery, and of Walker on natural history are still in existence. At Edinburgh, Tennant came into intimate relationship not only with Black but also with Hutton the geologist, Playfair the mathematician and Webb Seymour and his friends, the Horners, and it may be that Tennant performed experiments under the direction of Black and Hutton designed to support the latter's theory of rock formation. Tennant's stay in Edinburgh and especially his close association with Black profoundly influenced his attitude to science, confirming him in his choice of chemistry as the sphere of his life's work and leading him to accompany Black about 1790 as among the very first British scientists to accept in full the implications of the antiphlogistic theory.

Tennant left Edinburgh in 1781 and entered the University of Cambridge, again as a medical student, first as a pensioner at Christ's College and then, in 1782, as a Fellow Commoner of Emmanuel College. In an age when Fellow Commoners were noted more for their profligacy than for studious habits, Tennant's dedication to the pursuit of scientific inquiry is outstanding, especially as he was now in complete control of his own fortunes. Tennant's close friends at Cambridge included Sir Busick Harwood, who occupied the chair of anatomy during 1785–1814 and was Downing professor of medicine during 1800–14, Isaac Milner, who became the first Jacksonian professor in 1793 and to whom Tennant lent his notes of Black's lectures on chemistry, Dr. Edward Waring, the Lucasian professor of mathematics, Whitehall Whitehall Davies, a close family friend of his boyhood, Thomas Smith, later of Easton Grey and friend of Ricardo and Malthus and John Whishaw, later the "Pope of Holland House", confidant of the most influential of Whig politicians and Tennant's lifelong correspondent. Both Milner and Waring sponsored his election to the fellowship of the Royal Society in 1785 when he was twenty-four, and all of them remained his close friends throughout his life. In 1788, he "kept his Acts" for the degree of M.B., and a historian of the period who knew him in College remarks that this Act and that for his M.D. in 1796 were "of the highest order though marked by great eccentricity".

In addition to his preoccupation with items of chemical research, Tennant, while at Cambridge, began his foreign travels. In 1784 he visited Denmark and Sweden with the object of becoming personally acquainted with Scheele, Gahn and Berzelius. The visit stimulated his interest in geology and mineralogy, especially as he learnt from Gahn the use of the blowpipe in mineral analysis and soon became an acknowledged expert. In 1786 he paid a visit to France, Holland and the Lowlands, where he met Berthollet, Delametherie and very probably Lavoisier. This tour enlarged and deepened his interest in political economy, a subject which fascinated him for the rest of his life. A further European tour in 1793 took him to Switzerland, where he met Gibbon, then living out his last years at Lausanne. Returning via Italy, Germany and France, he remarked that most of the German chemists he had met appeared still to be preoccupied with the search for the 'philosopher's stone'. About this time, Tennant was asked to stand as a candidate for the Jacksonian professorship at Cambridge, but withdrew his name later. F. J. H. Wollaston was eventually elected.

Shortly after taking his degree in 1788, Tennant left Cambridge to reside in London at 4, Garden Court, Temple, and began to engage in chemical research, to attend meetings of learned societies and to build up a wider and wider circle of friends and acquaintances among the scientists, political economists and political reformers of the day. He never practised medicine, although he seems to have been very much attracted to the works and opinions of Sydenham and the chemical aspects of disease. His personal fortune, his love of independence and hatred of restraint, his sensitive nature and benevolent personality stifled in him any desire to undertake the drudgery of the life of a practising physician, and added to this there was the growing success attending his private researches. Between 1791 and 1797 he read papers before the Royal Society on the decomposition of fixed air, the nature of diamond and the action of nitre on gold and platina, all showing his growing mastery of research methods and in concept and design and showing, too, the strong influences of Black and the Edinburgh school of chemistry, the new ideas of chemical philosophy originating in the French school under Lavoisier and bearing, within the results, the seeds of greater triumphs in the future.

At this period of his life, Tennant's situation was indeed an enviable one. Rich enough to follow his own inclinations, he was at peace with himself because of his decision to devote himself to chemical research, was well established in London as a scientist of repute, and by the charm and benevolence of his personality was the centre of a widening circle of intellectual and influential friends. John Whishaw had come to live near him and through his friendship Tennant moved among the members of the Whig party at Holland House, while Francis Horner lived very near him in the Temple. The only ill-fortune was a gradual decline in his health, and even this turned out for the best, for, on being urged to cultivate more interests, he took up horse riding, in which he had not indulged since his mother's tragic death. This new form of exercise, which he continued to practise for the rest of his life, not only restored his health, but also started him off on a new venture. He became so interested in farming that, after experimenting for a year or two with a few acres of land near Epworth in Lincolnshire, he purchased 500 acres of land newly allocated under the Enclosure Act at Shipham in Somerset. On this land, Tennant built a small country house in which he lived every summer and entertained his friends. His interest in farming was not in growing crops, but in conducting agricultural experiments, and his experiences led to the publication of his paper on the different sorts of lime used in agriculture with special reference to the deleterious effect on crops of magnesium limestone.

So, from about 1800 onwards, Tennant's life moved within two circles, each with its own friends and acquaintances but at times overlapping, one predominantly scientific and the other centred around politics and political economy. The latter included Thomas Smith, and his home at Easton Grey in Wiltshire, which was within easy travelling distance of Tennant's country house. He was a constant visitor at Easton Grey, where he was held in the greatest personal esteem and where he became friendly with Ricardo and Malthus. The political circle also included Whishaw, Warburton, Sharp, Rogers, Dumont, Sir Samuel Romilly, Sir J. Mackintosh, Lord Brougham and Francis Horner, and others who moved among the Whigs of Holland House and belonged to a select dining club called the 'King of Clubs'. Here the talk was of reform and theories of political economy, and Tennant's interest was so aroused that he offered to found a chair of political economy at Cambridge and contemplated writing a treatise which would embody his views on the subject with reference both to Britain and to other European countries.

This increasing preoccupation with political economy and reform did not, however, affect in any way his scientific activities. His paper on the composition of emery published in 1802 gives evidence of his continuing experimental work, but a more important feature of his scientific life is the deepening of his friendship with W. H. Wollaston, which blossomed into active collaboration and partnership during the next ten years. The friendship between the two men began at Cambridge, where Wollaston was a Pensioner and Scholar at Gonville and Caius College from 1782, graduating M.B. in 1787. He, too, attended Milner's lectures on chemistry and was taught the use of the blowpipe in mineral analysis by Tennant himself. During 1787–97 Wollaston was practising medicine in Huntingdon and Bury St. Edmunds, but when he went to London permanently in 1797, in order to pursue the calling of physician, the friendship was renewed and became intimate enough for Wollaston to act as Tennant's assistant during his experiments on the analysis of the diamond in 1797. It may be that this fruitful collaboration was a real factor, as well as the well-known incident at St. George's Hospital, in influencing Wollaston in his decision to give up a career in medicine for one devoted to chemical research. Indeed, there is evidence that Tennant's influence on Wollaston at this period of his life was very profound, for Warburton wrote in his biography of Wollaston that "Wollaston held Tennant's knowledge of the sciences in profound admiration and a few years after this time expressed his despair of ever becoming Tennant's equal as a Chemist".

From at least 1800 until his death in 1815, Tennant was both a financial and a scientific partner of Wollaston, a collaboration which brought fame to both men and success in many spheres of scientific achievement. The most spectacular result of the collaboration was achieved by the successful outcome of the series of experiments, initiated by a further study of Tennant's paper on the action of nitre on platina, which resulted in Tennant's discovery and extraction of osmium and iridium from crude platina, and Wollaston's discovery and extraction of palladium and rhodium. For this discovery Tennant was awarded the Copley Medal of the Royal Society, and Wollaston went on to develop his well-known method of producing malleable platinum and so pure platinum sheet. There is some evidence to suggest that this method may have owed something to Tennant's friendship with Black at Edinburgh. The practical result, however, was that the two men proceeded to make and sell the first platinum stills for use in the manufacture and purification of sulphuric acid. A further successful venture which lasted until 1811 was the manufacture of oxalic acid and oxalates, tartaric and citric acids from argol and lemon juice.

To this partnership, Tennant contributed money, a wealth of scientific acumen and knowledge and some practical skill, but it was Wollaston who contributed more and more of all three as time went on. Indeed, during the partnership, Tennant began increasingly to show something of that trait in his character on which all his friends have commented—the exhibition of a sense of a lack of purpose, a carelessness sometimes amounting almost to indolence which seemed to take possession of him and seemed to them to be akin to that shown by Dr. Black himself. The friendship, however, remained firm and close, because Tennant and Wollaston visited Ireland together in 1805. Tennant repeated the visit in 1806, but this time with W. G. Browne, the celebrated African traveller and explorer, another whose friendship Tennant valued highly until Browne's assassination near Tabriz in 1813. This friendship led to a similar one with the explorer Burkhardt, who died in 1809.

In addition to being a Fellow of the Royal Society and a member of the Royal Institution, Tennant was a founder member of the Askesian Society (1799), renamed the Geological Society in 1806 In 1811, Tennant contributed a short note to the Society on native concrete boracic acid, and in 1813, when he was a vice-president, he delivered a lecture to the Society on the principles of mineralogy. in which he expressed his great indebtedness to the views expressed by Berzelius, who had stayed with him at his farm in 1812

The success of this lecture, and those which Tennant was accustomed to give on chemistry and mineralogy to quite large gatherings of his friends in his rooms at Garden Court, together with his outstanding scientific achievements, convinced his friends of his suitability as a candidate for the professorship of chemistry at Cambridge, and in 1813 he was elected to the chair, following Farish, who had been elected to the Jacksonian professorship

During the remaining two years of his life, Tennant divided his time between Cambridge, London and his farm at Shipham Letters in existence show a ripening friendship between Tennant and Berzelius after the latter's visit to England in 1812, and they throw light, too, on his friendship with the scientists Thomas Young, Marcet, Dr McMichael and Sir James Sebright

Tennant was involved in an interesting experience which may have had later important repercussions An explosion occurred in a gas-holder belonging to the Gas Light Co in 1813 In 1814, a committee from the Royal Society was charged with investigating the matter, and, Tennant, who was a member of the Council of the Society, and another (Wollaston ?), after a great deal of experimental work, showed that a flame will not pass through thin tubes and ignite an explosive mixture. Davy repeated these experiments in the following year and from the results discovered the use of gauze in the manufacture of the safety lamp Dr Marcet, writing to Berzelius in 1816, implies that Davy knew of Tennant's previous work but Davy always denied this

Tennant's election as professor of chemistry at Cambridge gave great satisfaction to all concerned and had a stimulating effect on Tennant himself Because of his scientific reputation and ability, and his personal qualities, it was confidently expected that he would establish and build up a notable school of chemistry in the University, and, but for his untimely death, there is every reason to think that this would have happened. His first course of lectures was attended by large audiences who were entertained and instructed by a masterly exposition of chemical principles illustrated by many experiments both of his own devising and also supplied by his many scientific friends. Among his first students were Charles Babbage and J W H Herschel During his short tenure of the professorship, Tennant revived an old interest in galvanism and built a much-improved voltaic battery embodying several unique features which he used with great success in his lectures He also developed a new method of manufacturing potassium and published the results of his very first piece of experimental research on double distillation It is now known that on the eve of his last Continental tour in 1814 he had completed two further pieces of research, one on the use of oxalic acid in the formation of sugar from starch and the other on the existence, extraction and purification of iodine from marine sources. He had also come to the conclusion that aragonite and calcite were dimorphic states of calcium carbonate, and he contemplated the publication of what would have been an important step in crystallography.

In September 1814 Tennant sailed for France, with Marcet and Wollaston, to enjoy a Continental holiday After touring southern France, meeting Berthellot and Berard in Marseilles and staying with scientific friends in Paris, he reached Boulogne on his way home on February 22, 1815 Strong winds prevented a boat from leaving the harbour and Tennant, accompanied by Baron Bulow, went riding on the sands While inspecting a small fort, a bridge over a deep ditch gave way under Tennant's horse, and as a result of this accident Tennant died in Boulogne hospital and was buried in Boulogne cemetery

So far as is known, no likeness of Tennant exists, but it is said that in his features he closely resembled the philosopher Locke He never married and seemed quite indifferent to female society Of his influence on the scientific events of his day, there can be no doubt of its prime importance, not only because of his own personal contributions, but also because of his influence on the work of other scientists, notably Davy and Wollaston—an influence which does not seem to have been adequately recognized or appreciated Of his character and personality, some words written by Brande and some by Dyer may be quoted Brande wrote in his *Manual of Chemistry* "Mr Smithson Tennant was a profound philosopher and a matchless companion His learning was without pedantry, and his wit without sarcasm He was deep but always clear, gentle but never dull. To those who knew him not, it is scarcely possible to offer an adequate representation of his singularly pleasing and enlightened character by those who enjoyed his acquaintance and partook of his social hours His extent of knowledge, his happy and unrivalled talent for conversation, his harmless but brilliant flashes of merriment and all his amiable peculiarities can never be forgotten" Dyer, who knew him at Cambridge, wrote "It is pleasing to pay respect to a person whose modesty surpassed his industry, whose love of science was greater than his love of fame and to whom nothing perhaps was wanting to have rendered him one of the most distinguished men of his time except better health and more systematic habits of study"

GENERAL NATURE OF THE GENETIC CODE FOR PROTEINS

By Dr. F. H. C. CRICK, F.R.S., LESLIE BARNETT, Dr. S. BRENNER
and Dr. R. J. WATTS-TOBIN

Medical Research Council Unit for Molecular Biology,
Cavendish Laboratory, Cambridge

THERE is now a mass of indirect evidence which suggests that the amino-acid sequence along the polypeptide chain of a protein is determined by the sequence of the bases along some particular part of the nucleic acid of the genetic material. Since there are twenty common amino-acids found throughout Nature, but only four common bases, it has often been surmised that the sequence of the four bases is in some way a code for the sequence of the amino-acids. In this article we report genetic experiments which, together with the work of others, suggest that the genetic code is of the following general type:

(*a*) A group of three bases (or, less likely, a multiple of three bases) codes one amino-acid.

(*b*) The code is not of the overlapping type (see Fig. 1).

(*c*) The sequence of the bases is read from a fixed starting point. This determines how the long sequences of bases are to be correctly read off as triplets. There are no special 'commas' to show how to select the right triplets. If the starting point is displaced by one base, then the reading into triplets is displaced, and thus becomes incorrect.

(*d*) The code is probably 'degenerate', that is, in general, one particular amino-acid can be coded by one of several triplets of bases.

The Reading of the Code

The evidence that the genetic code is not overlapping (see Fig. 1) does not come from our work but from that of Wittmann[1] and of Tsugita and Fraenkel-Conrat[2] on the mutants of tobacco mosaic virus produced by nitrous acid. In an overlapping triplet code, an alteration to one base will in general change three adjacent amino-acids in the polypeptide chain. Their work on the alterations produced in the protein of the virus show that usually only one amino-acid at a time is changed as a result of treating the ribonucleic acid (RNA) of the virus with nitrous acid. In the rarer cases where two amino-acids are altered (owing presumably to two separate deaminations by the nitrous acid on one piece of RNA), the altered amino-acids are not in adjacent positions in the polypeptide chain.

Brenner[3] had previously shown that, if the code were universal (that is, the same throughout Nature), then all overlapping triplet codes were impossible. Moreover, all the abnormal human hæmoglobins studied in detail[4] show only single amino-acid changes. The newer experimental results essentially rule out all simple codes of the overlapping type.

If the code is not overlapping, then there must be some arrangement to show how to select the correct triplets (or quadruplets, or whatever it may be) along the continuous sequence of bases. One obvious suggestion is that, say, every fourth base is a 'comma'. Another idea is that certain triplets make 'sense', whereas others make 'nonsense', as in the comma-free codes of Crick, Griffith and Orgel[5]. Alternatively, the correct choice may be made by starting at a fixed point and working along the sequence of bases three (or four, or whatever) at a time. It is this possibility which we now favour.

Experimental Results

Our genetic experiments have been carried out on the *B* cistron of the r_{II} region of the bacteriophage *T*4, which attacks strains of *Escherichia coli*. This is the system so brilliantly exploited by Benzer[6,7]. The r_{II} region consists of two adjacent genes, or 'cistrons', called cistron *A* and cistron *B*. The wild-type phage will grow on both *E. coli B* (here called *B*) and on *E. coli K*12 (λ) (here called *K*), but a phage which has lost the function of either gene will not grow on *K*. Such a phage produces an *r* plaque on *B*. Many point mutations of the genes are known which behave in this way. Deletions of part of the region are also found. Other mutations, known as 'leaky', show partial function; that is, they will grow on *K* but their plaque-type on *B* is not truly wild. We report here our work on the mutant *P* 13 (now re-named *FC* 0) in the *B*1 segment of the *B* cistron. This mutant was originally produced by the action of proflavin[8].

We[9] have previously argued that acridines such as proflavin act as mutagens because they add or delete a base or bases. The most striking evidence in favour of this is that mutants produced by acridines are seldom 'leaky', they are almost always completely lacking in the function of the gene. Since our note was published, experimental data from two sources have been added to our previous evidence: (1) we have examined a set of 126 r_{II} mutants made with acridine yellow, of these only 6 are leaky (typically about half the mutants made with base analogues are leaky), (2) Streisinger[10] has found that whereas mutants of the lysozyme of phage *T*4 produced by base-analogues are usually leaky, all lysozyme mutants produced by proflavin are negative, that is, the function is completely lacking.

If an acridine mutant is produced by, say, adding a base, it should revert to 'wild-type' by deleting a base. Our work on revertants of *FC* 0 shows that it usually

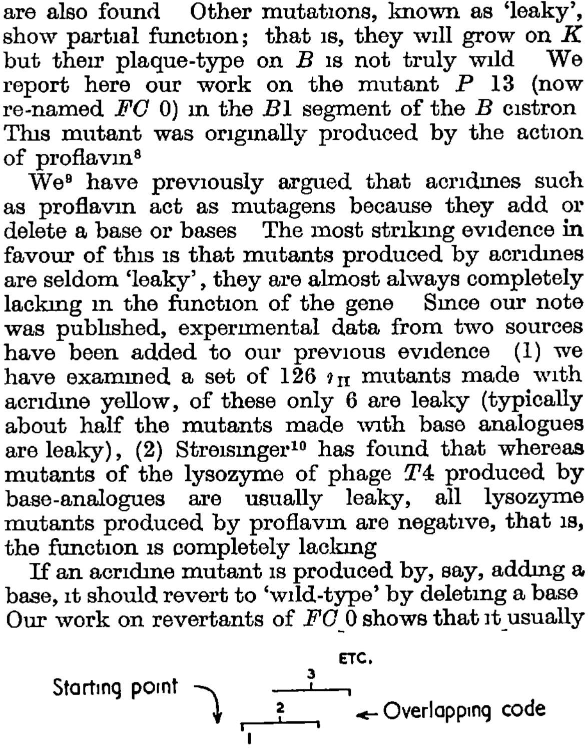

Fig. 1. To show the difference between an overlapping code and a non-overlapping code. The short vertical lines represent the bases of the nucleic acid. The case illustrated is for a triplet code.

reverts not by reversing the original mutation but by producing a second mutation at a nearby point on the genetic map. That is, by a 'suppressor' in the same gene. In one case (or possibly two cases) it may have reverted back to true wild, but in at least 18 other cases the 'wild type' produced was really a double mutant with a 'wild' phenotype. Other workers[11] have found a similar phenomenon with r_{II} mutants, and Jinks[12] has made a detailed analysis of suppressors in the h_{III} gene.

The genetic map of these 18 suppressors of *FC* 0 is shown in Fig. 2, line *a*. It will be seen that they all fall in the *B*1 segment of the gene, though not all of them are very close to *FC* 0. They scatter over a region about, say, one-tenth the size of the *B* cistron. Not all are at different sites. We have found eight sites in all, but most of them fall into or near two close clusters of sites.

In all cases the suppressor was a non-leaky *r*. That is, it gave an *r* plaque on *B* and would not grow on *K*. This is the phenotype shown by a complete deletion of the gene, and shows that the function is lacking. The only possible exception was one case where the suppressor appeared to back-mutate so fast that we could not study it.

Each suppressor, as we have said, fails to grow on *K*. Reversion of each can therefore be studied by the same procedure used for *FC* 0. In a few cases these mutants apparently revert to the original wild-type, but usually they revert by forming a double mutant. Fig. 2, lines *b*–*g*, shows the mutants produced as suppressors of these suppressors. Again all these new suppressors are non-leaky *r* mutants, and all map within the *B*1 segment for one site in the *B*2 segment.

Once again we have repeated the process on two of the new suppressors, with the same general results, as shown in Fig. 2, lines *i* and *j*.

All these mutants, except the original *FC* 0, occurred spontaneously. We have, however, produced one set (as suppressors of *FC* 7) using acridine yellow as a mutagen. The spectrum of suppressors we get (see Fig. 2, line *h*) is crudely similar to the spontaneous spectrum, and all the mutants are non-leaky *r*'s. We have also tested a (small) selection of all our mutants and shown that their reversion-rates are increased by acridine yellow.

Thus in all we have about eighty independent *r* mutants, all suppressors of *FC* 0, or suppressors of suppressors, or suppressors of suppressors of suppressors. They all fall within a limited region of the gene and they are all non-leaky *r* mutants.

The double mutants (which contain a mutation plus its suppressor) which plate on *K* have a variety of plaque types on *B*. Some are indistinguishable from wild, some can be distinguished from wild with difficulty, while others are easily distinguishable and produce plaques rather like *r*.

We have checked in a few cases that the phenomenon is quite distinct from 'complementation', since the two mutants which separately are phenotypically *r*, and together are wild or pseudo-wild,

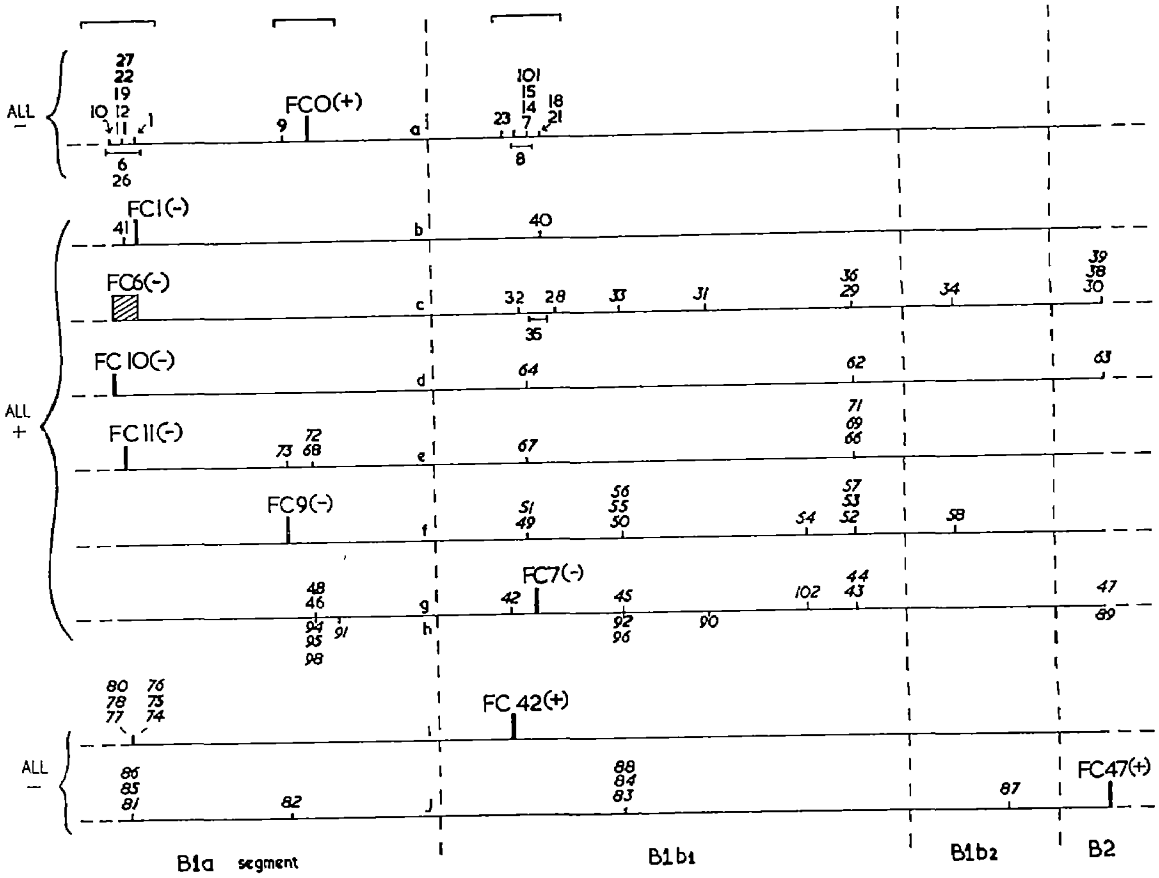

Fig. 2. A tentative map—only very roughly to scale—of the left-hand end of the *B* cistron, showing the position of the *FC* family of mutants. The order of sites within the regions covered by brackets (at the top of the figure) is not known. Mutants in italics have only been located approximately. Each line represents the suppressors picked up from one mutant, namely, that marked on the line in bold figures

must be put together in the same piece of genetic material A simultaneous infection of *K* by the two mutants in separate viruses will not do

The Explanation in Outline

Our explanation of all these facts is based on the theory set out at the beginning of this article. Although we have no direct evidence that the *B* cistron produces a polypeptide chain (probably through an RNA intermediate), in what follows we shall assume this to be so To fix ideas, we imagine that the string of nucleotide bases is read, triplet by triplet, from a starting point on the left of the *B* cistron We now suppose that, for example, the mutant *FC* 0 was produced by the insertion of an additional base in the wild-type sequence. Then this addition of a base at the *FC* 0 site will mean that the reading of all the triplets to the right of *FC* 0 will be shifted along one base, and will therefore be incorrect Thus the amino-acid sequence of the protein which the *B* cistron is presumed to produce will be completely altered from that point onwards This explains why the function of the gene is lacking To simplify the explanation, we now postulate that a suppressor of *FC* 0 (for example, *FC* 1) is formed by deleting a base Thus when the *FC* 1 mutation is present by itself, all triplets to the right of *FC* 1 will be read incorrectly and thus the function will be absent However, when both mutations are present in the same piece of DNA, as in the pseudo-wild double mutant *FC* (0 + 1), then although the reading of triplets between *FC* 0 and *FC* 1 will be altered, the original reading will be restored to the rest of the gene This could explain why such double mutants do not always have a true wild phenotype but are often pseudo-wild, since on our theory a small length of their amino-acid sequence is different from that of the wild-type.

For convenience we have designated our original mutant *FC* 0 by the symbol + (this choice is a pure convention at this stage) which we have so far considered as the addition of a single base The suppressors of *FC* 0 have therefore been designated – The suppressors of these suppressors have in the same way been labelled as +, and the suppressors of these last sets have again been labelled – (see Fig 2)

Starting point

Fig 3 To show that our convention for arrows is consistent The letters *A*, *B* and *C* each represent a different base of the nucleic acid For simplicity a repeating sequence of bases, *ABC*, is shown (This would code for a polypeptide for which every amino-acid was the same) A triplet code is assumed The dotted lines represent the imaginary 'reading frame' implying that the sequence is read in sets of three starting on the left

Double Mutants

We can now ask What is the character of any double mutant we like to form by putting together in the same gene any pair of mutants from our set of about eighty ? Obviously, in some cases we already know the answer, since some combinations of a + with a – were formed in order to isolate the mutants But, by definition, no pair consisting of one + with another + has been obtained in this way, and there are many combinations of + with – not so far tested

Now our theory clearly predicts that all combinations of the type + with + (or – with –) should give an *r* phenotype and not plate on *K* We have put together 14 such pairs of mutants in the cases listed in Table 1 and found this prediction confirmed.

Table 1. DOUBLE MUTANTS HAVING THE *r* PHENOTYPE

– With –	+ With +	
FC (1 + 21)	*FC* (0 + 58)	*FC* (40 + 57)
FC (23 + 21)	*FC* (0 + 38)	*FC* (40 + 58)
FC (1 + 23)	*FC* (0 + 40)	*FC* (40 + 55)
FC (1 + 9)	*FC* (0 + 55)	*FC* (40 + 54)
	FC (0 + 54)	*FC* (40 + 38)

At first sight one would expect that all combinations of the type (+ with –) would be wild or pseudo-wild, but the situation is a little more intricate than that, and must be considered more closely. This springs from the obvious fact that if the code is made of triplets, any long sequence of bases can be read correctly in one way, but incorrectly (by starting at the wrong point) in two different ways, depending whether the 'reading frame' is shifted one place to the right or one place to the left

If we symbolize a shift, by one place, of the reading frame in one direction by → and in the opposite direction by ←, then we can establish the convention that our + is always at the head of the arrow, and our – at the tail This is illustrated in Fig 3

We must now ask Why do our suppressors not extend over the whole of the gene ? The simplest postulate to make is that the shift of the reading frame produces some triplets the reading of which is 'unacceptable', for example, they may be 'nonsense', or stand for 'end the chain', or be unacceptable in some other way due to the complications of protein structure. This means that a suppressor of, say, *FC* 0 must be within a region such that no 'unacceptable' triplet is produced by the shift in the reading frame between *FC* 0 and its suppressor. But, clearly, since for any sequence there are *two* possible misreadings, we might expect that the 'unacceptable' triplets produced by a → shift would occur in different places on the map from those produced by a ← shift.

Examination of the spectra of suppressors (in each case putting in the arrows → or ←) suggests that while the → shift is acceptable anywhere within our region (though not outside it) the shift ←, starting from points near *FC* 0, is acceptable over only a more limited stretch. This is shown in Fig 4. Somewhere in the left part of our region, between *FC* 0 or *FC* 9 and the *FC* 1 group, there must be one or more unacceptable triplets when a ← shift is made; similarly for the region to the right of the *FC* 21 cluster Thus we predict that a combination of a + with a − will be wild or pseudo-wild if it involves a → shift, but that such pairs involving a ← shift will be phenotypically *r* if the arrow crosses one or more of the forbidden places, since then an unacceptable triplet will be produced

Table 2 DOUBLE MUTANTS OF THE TYPE (+ WITH −)

+ / −	*FC* 41	*FC* 0	*FC* 40	*FC* 42	*FC* 58*	*FC* 63	*FC* 38
FC 1	*W*	*W*	*W*		W		W
FC 86		W	W	W	W	W	
FC 9	*r*	*W*	W	W	*W*		W
FC 82	*r*		W	W	W	W	
FC 21	*r*	*W*			W		W
FC 88	*r*	*r*			W	W	
FC 87	*r*	*r*	*r*	*r*			W

W, wild or pseudo-wild phenotype, *W*, wild or pseudo-wild combination used to isolate the suppressor, *r*, *r* phenotype

* Double mutants formed with *FC* 58 (or with *FC* 34) give sharp plaques on *K*.

We have tested this prediction in the 28 cases shown in Table 2 We expected 19 of these to be wild, or pseudo-wild, and 9 of them to have the *r* phenotype In all cases our prediction was correct We regard this as a striking confirmation of our theory It may be of interest that the theory was constructed before these particular experimental results were obtained

Rigorous Statement of the Theory

So far we have spoken as if the evidence supported a triplet code, but this was simply for illustration Exactly the same results would be obtained if the code operated with groups of, say, 5 bases Moreover, our symbols + and − must not be taken to mean literally the addition or subtraction of a single base

It is easy to see that our symbolism is more exactly as follows

+ represents $+m$, modulo n
− represents $-m$, modulo n

where n (a positive integer) is the coding ratio (that is, the number of bases which code one amino-acid) and m is any integral number of bases, positive or negative

It can also be seen that our choice of reading direction is arbitrary, and that the same results (to a first approximation) would be obtained in whichever direction the genetic material was read, that is, whether the starting point is on the right or the left of the gene, as conventionally drawn

Triple Mutants and the Coding Ratio

The somewhat abstract description given above is necessary for generality, but fortunately we have convincing evidence that the coding ratio is in fact 3 or a multiple of 3

This we have obtained by constructing triple mutants of the form (+ with + with +) or (− with − with −) One must be careful not to make shifts across the ‘unacceptable’ regions for the ← shifts, but these we can avoid by a proper choice of mutants

Table 3 TRIPLE MUTANTS HAVING A WILD OR PSEUDO-WILD PHENOTYPE

FC (0 + 40 + 38)
FC (0 + 40 + 58)
FC (0 + 40 + 57)
FC (0 + 40 + 54)
FC (0 + 40 + 55)
FC (1 + 21 + 23)

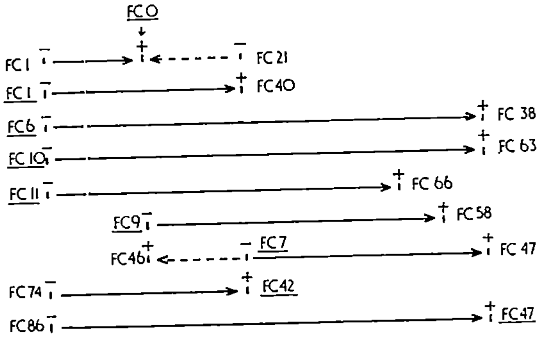

Fig 4 A simplified version of the genetic map of Fig 2 Each line corresponds to the suppressor from one mutant, here underlined The arrows show the range over which suppressors have so far been found, the extreme mutants being named on the map Arrows to the right are shown solid, arrows to the left dotted

We have so far examined the six cases listed in Table 3 and in all cases the triples are wild or pseudo-wild.

The rather striking nature of this result can be seen by considering one of them, for example, the triple (*FC* 0 with *FC* 40 with *FC* 38) These three mutants are, by themselves, all of like type (+). We can say this not merely from the way in which they were obtained, but because each of them, when combined with our mutant *FC* 9 (—), gives the wild, or pseudo-wild phenotype However, either singly or together in pairs they have an *r* phenotype, and will not grow on *K* That is, the function of the gene is absent Nevertheless, the combination of all three in the same gene partly restores the function and produces a pseudo-wild phage which grows on *K*

This is exactly what one would expect, in favourable cases, if the coding ratio were 3 or a multiple of 3

Our ability to find the coding ratio thus depends on the fact that, in at least one of our *composite* mutants which are ‘wild’, at least one amino-acid must have been added to or deleted from the polypeptide chain without disturbing the function of the gene-product too greatly

This is a very fortunate situation The fact that we can make these changes and can study so large a region probably comes about because this part of the protein is not essential for its function That this is so has already been suggested by Champe and Benzer[13] in their work on complementation in the r_{II} region By a special test (combined infection on *K*, followed by plating on *B*) it is possible to examine the function of the *A* cistron and the *B* cistron separately. A particular deletion, 1589 (see Fig. 5) covers the right-hand end of the *A* cistron and part of the left-hand end of the *B* cistron Although 1589 abolishes the *A* function, they showed that it allows the *B* function to be expressed to a considerable extent The region of the *B* cistron deleted by 1589 is that into which all our *FC* mutants fall

Joining two Genes Together

We have used this deletion to re-inforce our idea that the sequence is read in groups from a fixed starting point Normally, an alteration confined to the *A* cistron (be it a deletion, an acridine mutant, or any other mutant) does not prevent the expression of the *B* cistron Conversely, no alteration within the *B* cistron prevents the function of the *A* cistron This implies that there may be a region between the two cistrons which separates them and allows their functions to be expressed individually

We argued that the deletion 1589 will have lost this separating region and that therefore the two (partly damaged) cistrons should have been joined together Experiments show this to be the case, for now an alteration to the left-hand end of the *A* cistron, if combined with deletion 1589, can prevent the *B* function from appearing This is shown in Fig 5 Either the mutant *P*43 or *X*142 (both of which revert strongly with acridines) will prevent the *B* function when the two cistrons are joined, although both of these mutants are in the *A* cistron This is also true of *X*142 *S*1, a suppressor of *X*142 (Fig 5, case *b*) However, the double mutant (*X*142 with *X*142 *S*1), of the type (+ with −), which by itself is pseudo-wild, still has the *B* function when combined with 1589 (Fig 5, case *c*) We have also tested in this way the 10 deletions listed by Benzer[7], which fall wholely to the left of 1589 Of these, three (386, 168 and 221) prevent the *B* function (Fig 5 case *f*), whereas the other seven show it (Fig 5, case *e*). We surmise that each of these seven has lost a number of bases which is a multiple of 3 There are theoretical reasons for expecting that deletions may not be random in length, but will more often have lost a number of bases equal to an integral multiple of the coding ratio

It would not surprise us if it were eventually shown that deletion 1589 produces a protein which consists of part of the protein from the *A* cistron and part of that from the *B* cistron, joined together in the same polypeptide chain, and having to some extent the function of the undamaged *B* protein

Is the Coding Ratio 3 or 6 ?

It remains to show that the coding ratio is probably 3, rather than a multiple of 3 Previous rather rough extimates[10,14] of the coding ratio (which are admittedly very unreliable) might suggest that the coding ratio is not far from 6 This would imply, on our theory, that the alteration in *FC* 0 was not to one base, but to two bases (or, more correctly, to an even number of bases)

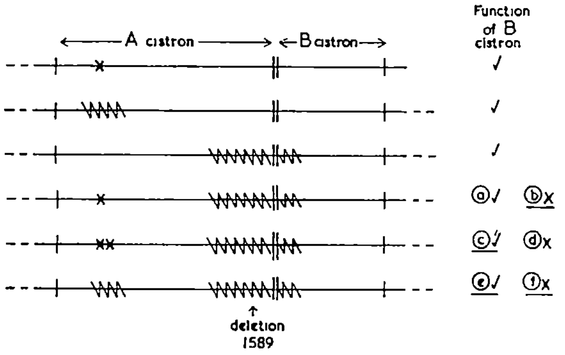

Fig 5 Summary of the results with deletion 1589 The first two lines show that without 1589 a mutation or a deletion in the *A* cistron does not prevent the *B* cistron from functioning Deletion 1589 (line 3) also allows the *B* cistron to function The other cases, in some of which an alteration in the *A* cistron prevents the function of the *B* cistron (when 1589 is also present), are discussed in the text They have been labelled (*a*), (*b*), etc , for convenience of reference, although cases (*a*) and (*d*) are not discussed in this paper ✓ implies function, × implies no function

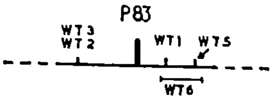

Fig 6 Genetic map of *P* 83 and its suppressors, *WT* 1, etc The region falls within segment *B*9*a* near the right-hand end of the *B* cistron It is not yet known which way round the map is in relation to the other figures

We have some additional evidence which suggests that this is unlikely First, in our set of 126 mutants produced by acridine yellow (referred to earlier) we have four independent mutants which fall at or close to the *FC* 9 site By a suitable choice of partners, we have been able to show that two are + and two are − Secondly, we have two mutants (*X*146 and *X*225), produced by hydrazine[15], which fall on or near the site *FC* 30 These we have been able to show are both of type −

Thus unless both acridines and hydrazine usually delete (or add) an even number of bases, this evidence supports a coding ratio of 3 However, as the action of these mutagens is not understood in detail, we cannot be certain that the coding ratio is not 6, although 3 seems more likely

We have preliminary results which show that other acridine mutants often revert by means of close suppressors, but it is too sketchy to report here A tentative map of some suppressors of *P* 83, a mutant at the other end of the *B* cistron, in segment *B* 9*a*, is shown in Fig. 6. They occur within a shorter region than the suppressors of *FC* 0, covering a distance of about one-twentieth of the *B* cistron The double mutant *WT* (2 + 5) has the *r* phenotype, as expected

Is the Code Degenerate?

If the code is a triplet code, there are 64 (4 × 4 × 4) possible triplets Our results suggest that it is unlikely that only 20 of these represent the 20 amino-acids and that the remaining 44 are nonsense If this were the case, the region over which suppressors of the *FC* 0 family occur (perhaps a quarter of the *B* cistron) should be very much smaller than we observe, since a shift of frame should then, by chance, produce a nonsense reading at a much closer distance This argument depends on the size of the protein which we have assumed the *B* cistron to produce We do not know this, but the length of the cistron suggests that the protein may contain about 200 amino-acids Thus the code is probably 'degenerate', that is, in general more than one triplet codes for each amino-acid. It is well known that if this were so, one could also account for the major dilemma of the coding problem, namely, that while the base composition of the DNA can be very different in different micro-organisms, the amino-acid composition of their proteins only changes by a moderate amount[16]. However, exactly how many triplets code amino-acids and how many have other functions we are unable to say

Future Developments

Our theory leads to one very clear prediction Suppose one could examine the amino-acid sequence of the 'pseudo-wild' protein produced by one of our double mutants of the (+ with −) type Conventional theory suggests that since the gene is only altered in two places, only two amino-acids would be changed Our theory, on the other hand, predicts that a string of amino-acids would be altered, covering the region of the polypeptide chain corresponding to the region on the gene between the two mutants. A good protein on which to test this hypothesis is the lysozyme of the phage, at present being studied chemically by Dreyer[17] and genetically by Streisinger[10].

At the recent Biochemical Congress at Moscow, the audience of Symposium I was startled by the announcement of Nirenberg that he and Matthaei[18] had produced polyphenylalanine (that is, a polypeptide all the residues of which are phenylalanine) by adding polyuridylic acid (that is, an RNA the bases of which are all uracil) to a cell-free system which can synthesize protein This implies that a sequence of uracils codes for phenylalanine, and our work suggests that it is probably a triplet of uracils

It is possible by various devices, either chemical or enzymatic, to synthesize polyribonucleotides with defined or partly defined sequences If these, too, will produce specific polypeptides, the coding problem is wide open for experimental attack, and in fact many laboratories, including our own, are already working on the problem. If the coding ratio is indeed 3, as our results suggest, and if the code is the same throughout Nature, then the genetic code may well be solved within a year

We thank Dr Alice Orgel for certain mutants and for the use of data from her thesis, Dr Leslie Orgel for many useful discussions, and Dr Seymour Benzer for supplying us with certain deletions We are particularly grateful to Prof C F. A Pantin for allowing us to use a room in the Zoological Museum, Cambridge, in which the bulk of this work was done

SCIENCE AND WORLD AFFAIRS

THE Seventh Pugwash Conference on Science and World Affairs was held at Stowe, Vermont, during September 5–9 Forty-one scientists from twelve countries attended the Conference*

This Conference had as its theme "International Co-operation in Pure and Applied Science". The previous conferences have been chiefly concerned with ways of preventing the misuse of science in the wholesale destruction of mankind In this Conference at Stowe, constructive international co-operation in science was discussed, because it is a way to create trust between nations, a trust which develops from common interests and from experience in working together

Science misused by nations to foster their competitive interests as world powers makes possible the destruction of mankind Science used co-operatively by all nations for the increase of human knowledge and the improvement of man's productive capacity can give all men on Earth a satisfactory and worthwhile life Scientists bear a responsibility both to foster the constructive use of science and to help in preventing its destructive use

The deliberations of the Conference were carried out in plenary sessions and in meetings of working groups Similar suggestions for co-operative research activities arose independently from different working groups, and this is reflected in several places in the statement This is a welcome indication of the essential unity in science The discussions were carried on in a spirit of friendly co-operation, and full agreement was reached by the entire Conference on the suggestions enumerated here

(I) Co-operation in the Earth Sciences

The planet Earth is the common abode of all humans. They have a common interest, both intellectual and practical, in increasing the knowledge of the structure and dynamics of the Earth

The following proposals were made by the Conference

(*A*) *A survey of the entire ocean in three dimensions*

(1) *The ocean floor* An international programme was proposed to develop a detailed map of the floor of the world ocean, including sub-bottom reflecting layers

(2) *Waters of the ocean* An international programme should be devised to survey and map the three-dimensional distribution of temperatures, salinity, density, dissolved oxygen, and nutrient salts, under average conditions, of the ocean and synoptic surveys to develop the broad picture of seasonal and shorter-period changes in more limited areas, as well as the study of the interactions among the major bodies of water in the ocean

(3) *Ocean life* An international survey and mapping showing the major biological provinces of the ocean and determination of the fertility of the waters at all levels in the food chain and the standing crop of food materials available for human use should be undertaken

(*B*) *Earth's crust and mantle Deep drilling programme* The objective of drilling through the

---

* Sir John Crawford (Australia), Prof Hans Thirring (Austria), Prof C Pavan (Brazil), Prof G Nadjakov (Bulgaria), Prof G Burkhardt (Federal Republic of Germany), Sir Edward Bullard, Prof A Haddow, Sir Ben Lockspeiser, Prof J Rotblat (Great Britain), Prof F B Straub (Hungary), Dr G Bernardini (Italy), Prof T Toyoda (Japan), Prof B V A Roling (Netherlands), Academician A A Blagonravov, Academician N N Bogolubov, Academician M M Dubinin, Prof V M Khvostov, Academician N M Sissakian, Prof N A Talensky, Academician I E Tamm, Academician A V Topchiev (U S S R), Prof Harrison Brown, Dr William Consolazio, Prof Paul Doty, Prof Bentley Glass, Prof C O'D Iselin, Dr Martin Kaplan, Prof Chauncey Leake, Prof Linus Pauling, Prof Jay Orear, Prof W Pickering, Mr Gerald Piel, Prof I Rabi, Prof Eugene Rabinowitch, Dr Roger Revelle, Prof Alexander Rich, Prof Walter Rosenblith, Dr Eugene Staley, Dr Alvin Weinberg, Prof Eugene Wigner, Prof J R Zacharias (United States)

Earth's crust to the mantle at selected points around the globe presents many unsolved technical problems which call for international collaboration It was agreed, therefore, that the calling of an international conference on these problems is an urgent first step.

(*C*) *Total environmental forecasting* An international conference should be called to consider and to organize the establishment of a world-wide network of radio-telemetering observational buoys This system of buoys would render continuous reports on atmospheric conditions and so contribute to the completion of the world weather map It would also continuously monitor the energy and water vapour energy exchange between the ocean and the atmosphere, and would observe the changes in the flow of ocean currents in three dimensions. Over a sufficiently long time-period, such a network of buoys would help to assign reliable values to the rate of overturn of the ocean as a whole, a key problem in both climatological forecasts and in the safe disposal of radioactive wastes at sea The hydrographic offices of the major maritime nations, as well as the World Meteorological Organization, should be encouraged to stimulate such a programme.

(*D*) *Resources* (1) *Fresh water* The rising world population and the increasing concentration of that population in metropolitan centres is already pressing on the water resources easily available for direct human consumption, for industrial purposes, and for agriculture It was agreed that an international conference should be called to consider the organization of an international hydrological decade for the study of the many unknowns that surround this ominous development

(2) *Living resources of the ocean* Acre per acre the oceans to-day sustain at least as large a plant crop on the average as does the land, yet man now gets only about 1 per cent of his food requirements from the sea The oceans, therefore, offer a means for the rapid solution of the protein deficiency afflicting two-thirds of the world population It is apparent that these resources can best be exploited to this end through international co-operation The ultimate aim should be to elevate the fishing industry from a hunting industry to an agricultural technology

(3) *Mineral resources of the ocean floor* Recent investigations of the ocean floor show a vast reserve of minerals, especially nickel, cobalt, copper and manganese By means of bottom-photography organized on a world-wide basis, the potentiality of this reserve may be more fully assessed The necessary observational programme could be organized by the Scientific Commission for Oceanographic Research.

(4) *Natural catastrophes* Earthquakes, tsunamis, volcanic eruptions, hurricanes and tornadoes constitute the principal hazards of this kind

With respect to the first three, a better international seismological network, including better instrumentation and distribution of stations, is required More detailed studies of hurricanes and tornadoes would reveal whether or not man can exert some control over these phenomena

To implement these programmes, it is recommended that in so far as possible existing international organizations be the means of furthering these programmes

(II) Co-operation in Space Research

Though the Conference felt that there should be close co-operation in space research it should be realized that complete co-operation in this field, as in some others, will become possible only when the arms race is ended, international tensions are reduced, complete and general disarmament becomes a reality, and the need for secrecy disappears But certain advances in the presently established co-operation in space are possible now, and certain others could be studied now with the hope of realization in the not too distant future

(*A*) First, an increase in the exchange of scientific information in areas such as the physics of space and the effects of the space environment on life is recommended It is further recommended that periodic international symposia be devoted to such subjects.

(*B*) The exchange of methods, and of information on instruments, for scientific space studies which have no military importance is also recommended.

(*C*) The orderly assignment and use of radio frequencies in space should be encouraged Strong support should be given to the initiative in this direction taken by the International Telecommunications Union, and it is to be hoped that a final solution can be reached within two years.

(*D*) The expansion of existing systems of satellite tracking stations is recommended Bilateral agreements between different nations, including (within the limits of military security) an agreement between the United States and the U S S R , on the common use of tracking stations; such a bilateral agreement could serve as the first step in this direction.

(*E*) International agreement should be reached on a co-ordinated programme for the use of rocket and satellite during the Quiet Sun Year (planned for the second half of 1962)

(*F*) Similar agreement should be reached on co-operation in the use of rockets and satellites in the projected world magnetic survey. This agreement should include arrangements for simultaneous observation from satellites launched into different orbits by different nations. This co-operation could be organized in the framework of the Committee on Space Research

(*G*) The desirability of international world-wide systems of communications satellites and of meteorological satellites is endorsed by the Conference, since these would clearly be in the interests of all mankind It is realized that certain difficulties now stand in the way, but it is to be hoped that the Governments of the United States and the U.S.S R , as well as of other nations embarking on rocket and satellite programmes, will undertake a common study of the ways to overcome them

(*H*) It is recommended that co-operation should be established in the instrumental study of the Moon, and also that the basic principles of the International Antarctic Treaty be applied to the Moon and other cosmic bodies

(*I*) The calling of an international conference or symposium to consider how to avoid the biological and radioactive contamination of extra-terrestrial bodies is strongly urged

(III) Co-operation in the Life Sciences

Among the many fields of biology in which international co-operation is possible, some are particularly well suited by their nature and importance for combined efforts These, which relate especially to the promotion of human welfare, have been given primary concern by the Conference

(*A*) *Biological aspects of food resources* One of the most important problems facing humanity is that of assuring an adequate supply of food Adequate biological information now exists to enhance considerably food production in low-yield areas. This can be done most effectively by the development of regional agricultural experiment stations, which can deal with the problem of developing agricultural methods suitable to the local terrain, as well as the long-term problem of breeding plants and animals which are able to thrive in the specific locality These local agricultural experiment stations should be co-ordinated with an international centre

It is recommended that existing marine biological laboratories be united into an international system perhaps under the International Union of Biological Sciences, to ensure permanent support and increase in number

(*B*) *Preservation and promotion of health* The health sciences offer one of the most rewarding meeting grounds for international co-operation in science Increased international co-operation and financial support are essential for the realization of important advances in such fields as cancer, cardiovascular disease, immunology. infectious diseases, mental health, environmental sanitation, problems of ageing, nutrition, human genetics, and others

International institutes of health devoted to these problems should be established in one carefully chosen place to serve as a world centre of medical research Smaller subsidiary institutes oriented towards more specialized problems or regional needs (space medicine, medical entomology, tropical medicine) should be established in different countries

(*C*) *The environment and its modification by man* The exponential growth of human populations and the accompanying industrial, agricultural and scientific activities have given rise to a number of serious problems, including pollution of air and water resources, which are of considerable biological importance Especially grave are the problems involving contamination of air, soil and water with radioactive substances Included here, as well as the more obvious problem of fall-out from nuclear explosions, there is the matter of the safe disposal of radioactive wastes More international attention should also be directed toward the problems of chemical pollution of air and water International conferences on these topics should be encouraged

The extinction of many plant and animal species seems possible There are large forest and game reserves in the newly formed African countries which are seriously threatened to-day because of a shortage of funds and trained personnel. This problem has been considered by a committee on ecology in the International Council of Scientific Unions A system of world-wide institutes should be established for preserving indigenous strains of plants, animals and micro-organisms

(*D*) '*Endless frontiers*' There has been a great development recently in our understanding of the structure and function of biological macromolecules and the central role of the nucleic acids and the mechanism which relates the nucleic acids to the protein molecules These developments have a significant bearing on the problems of cancer as well as the broader fields of molecular evolution and the origin of life Intense interest in this field has developed among scientists in all countries, and it may be possible to capitalize on this enthusiasm by developing an intercontinental institute of molecular biology.

Both the United States and the U S S R have announced that they are planning to carry out manned exploration of space It is not unreasonable to suggest that some of the biological developmental work be carried out in common A considerable saving of time and money would ensue from joint research projects in this area In addition, some of the instruments which man uses in space for his scientific investigations could be included in this co-operative programme Joint precautions must be exerted to prevent the contamination of extra-terrestrial bodies by terrestrial organisms

At the present time an International Biological Programme is under discussion by the International Council of Scientific Unions Many of the projects described above may be included in the Programme, which if carried out broadly and effectively, would have considerable scientific value as well as a favourable impact on public opinion

(IV) Co-operation in the Physical Sciences

Modern physical science has in many of its aspects become very big and expensive It therefore lends itself particularly well to intercontinental co-operation in which the costs are shared and the results are made available to all mankind

Four specific areas of physical science were identified as being ripe for vigorous action on an intercontinental basis These areas are the following

(*A*) *High-energy physics* Co-operation could centre around the establishment of a laboratory the main research tool of which would be an accelerator of not less than 300 × 10^9 eV and of a design which would achieve success in the shortest possible time.

(*B*) *Controlled thermonuclear and plasma research* In the field of controlled thermonuclear research there has been much effective exchange of information and scientists. This development is particularly significant since this research, prior to 1955, was secret It is urged that such collaboration be broadened, in particular, that the world's thermonuclear laboratories remain open to scientists of all nations who can contribute to this interesting and potentially important field of research

Although a new, very large thermonuclear device is probably not needed immediately, still there is a large field of general research in plasma physics which could well be advanced by the establishment of an intercontinental laboratory

(*C*) *Ultra-heavy element chemistry.* Two different devices are needed for such investigations high-flux reactors, and heavy-ion, high-current cyclotrons.

It is recommended that an intercontinental centre devoted to investigation of the properties of the ultra-heavy elements be established The centre probably should be equipped with the most powerful available heavy-ion cyclotron and with equipment for handling the materials The ultra high-flux reactor (10^{16} neutrons/cm ^{2}/sec), because of its hazard, probably should be located at a different, more isolated site

(*D*) *Large-scale computers* The development of the large modern electronic computer with its enormous memory and high speeds represents one of the most significant scientific events of the past two decades The future development of these computing machines, with larger memories and higher speeds by orders of magnitudes, would be of immense value to science Such computing machines will cost perhaps as much as 100 × 10^6 dollars

The development of such computers would be a suitable project for international co-operation The utilization of such a machine will advance not only mathematics but also all the physical sciences and the biological sciences, particularly the unravelling of the structure of macromolecules It would also find great utility in economics and other social sciences

(*E*) *A globular cluster of big science centres* It is believed that the separate big science laboratories in high-energy physics, heavy-element chemistry, macromolecular biology, health research, and possibly thermonuclear research, will prosper better if they are reasonably close together than if they are completely isolated from each other. The intercontinental computing centre will be more viable and will be a better centre if it were the nucleus of such a cluster.

The Conference urged that the intercontinental scientific laboratories be located in relative geographical proximity and that they be served by the intercontinental computing centre Such a centre, comprising much of what is called 'big science', would represent a capital investment of about 5×10^9 dollars It is believed that the astute location of such a striking epitome of science—the most characteristic theme of our modern civilization—could have extraordinarily great significance in improving the tone of the present political situation

(V) Co-operation in Assistance to Developing Nations

Assistance to developing countries is a duty and necessity for all countries This aid should be rendered so that it would not impair the independence of any country

Greater support for international co-operation in assistance to developing nations is needed Such co-operation could help to reduce world tensions, to strengthen peace, and to further disarmament Disarmament would in turn improve the climate for international co-operation in this and other fields and make available additional funds which could and would be used to increase the assistance to developing nations Clearly, the greatest co-operation and the release of maximum funds for the assistance programme could be achieved by complete disarmament

Scientists have a definite part to play in the development of assistance programmes and special emphasis should be placed on this subject in subsequent conferences Such a conference should include a large participation of representatives from the developing nations

The recommendation from the Economic and Social Council that a conference on science and technology in application to the problems of new nations should be held next summer in Geneva under United Nations sponsorship is to be welcomed

A subject of interest to scientists is that of natural resources of different areas and of their population trends Unprejudiced quantitative study of the latter topic should be carried out on an international, co-operative basis Another topic for similar co-operative research is world nutrition, including the study of reasons for widespread occurrence of avoidable malnutrition in many parts of the world. The problems of energy supply, particularly in areas in which the demand for energy is diffused rather than concentrated in large industrial centres, calls for a similar study It is suggested that preliminary study groups on these problems be organized prior to the above-mentioned conference

An international study should also be made of the advisability and practicability of establishing an international fund to which individual scientists from countries in which local funds are insufficient for this purpose could apply for assistance in their scientific research

(VI) Exchange of Scientists and Scientific Information

By its very nature and tradition science is a universal enterprise The rapid exchange of information mutual visits of scientists and their working as guests in the laboratories of other scientists constitute the main pathways of scientific collaboration among scientists all over the world It is to be noted that there has been substantial progress in recent years in the area of scientific exchange Yet it is to be regretted that there exists a number of difficulties which interfere in major ways with the further broadening of scientific collaboration and exchange

(*A*) *Exchange of scientists* The planned exchange of scientific personnel initiated by the Bronk–Nesmeyanov and similar agreements should be considerably increased The visits should be extended over periods sufficient for the completion of research projects In addition to planned exchange, the framework of these agreements should allow for and encourage invitations to scientists in the country in which they are to visit, and for the invited scientists to be able to accept such invitations Application of the *quid pro quo* principle to visits under the agreement (that is the exchange of one solid-state physicist for another solid-state physicist, etc) has tended to hamper fruitful exchange, and it is urged that such regulations be set aside in future agreements.

The role of Government bureaucracies in the administration of these agreements should be minimized To implement this recommendation, governments should be urged to expedite visas and passports for scientists since past and present failures in this respect have seriously hampered scientific exchange The scientific organizations of various nations should consider ways to facilitate the travel of pre- and post-doctoral fellows across national boundaries to study for adequate periods of time (one year or more) at research centres and under teachers where their training and scientific maturation can be best enhanced

(*B*) *Exchange of information* Noting the obstacle to the exchange of scientific information presented by the mounting volume of current publication, which is increasing exponentially and doubling about every decade, the situation calls for radical measures of rationalization Among potentially useful measures are the following to review and co-ordinate the character and content of journals published in all countries with the view of reducing the number of journals which a scientist must follow to keep abreast of work in his discipline, to institute standard formats for the presentation of scientific papers, to formulate a standard system for the annotation of the contents of published papers suitable for coding and manipulation by machines for the storage and retrieval of information, to institute regional depots under international co-ordination to store complete experimental records and other documentation in support of the brief published papers; to make such material rapidly available to interested scientists; to consolidate the abstracting services now carried on independently in many countries, a measure that could reduce present duplication of effort by a conservatively estimated factor of three

The publication of international review journals of two types as follows is recommended interdisciplinary review journals written in relatively non-technical language for the benefit of scientists in different disciplines, and more specialized review journals which would keep scientists working in a given area abreast of the work going on in the same or related areas all over the world.

All Governments are recommended to open their postal systems to the untrammelled flow of scientific publications whatever their country of origin or destination

LAND USE IN ARID REGIONS

THE arid zone programme of the United Nations Educational, Scientific and Cultural Organization, one of the Organization's three major projects, has yielded several valuable reviews of research and proceedings of symposia, mostly devoted to hydrology and ecology The latest in the series, a volume of some 350,000 words reviewing the history of land use in arid regions, is of more general interest* It deals with all the main dry lands with two main exceptions, those surrounding Abyssinia and those of South America in post-Columbian times

F K Hare explains the widespread aridity in sub-tropical latitudes in terms of the divergent wind-flow at low levels related to high pressure at 2–3 km, and considers it unlikely that any past climatic epoch can have been free of tropical aridity He finds it inconceivable that man can significantly alter the régime, the energy transformations involved are on so large a scale Thus the flooding of desert depressions, for example, would have only very modest effects on neighbouring areas

A summary by K W Butzer of what is known about climatic change in arid lands since the Pliocene sets the regional histories in a longer time perspective Full aridity was achieved in most arid lands some 15,000 years ago Since then there has been no progressive desiccation, only minor fluctuations of climate Of especial interest are those fluctuations which might possibly have affected the environment of man when he was first beginning to manage crops and animals in south-west Asia ten thousand years ago and in Mexico possibly not much later

Changes in climate over the past two or three thousand years are scarcely detectable with certainty until the fluctuation of the past three centuries This has involved more than the spectacular rapid advance and current retreat of Alpine glaciers, for it is becoming clear that semi-arid lands in many parts of the world have been receiving less rain in recent decades than in the latter half of the nineteenth century The dry trend continues, and the further outlook is unsettled

Prof Dudley Stamp, the editor of the volume, points out that a knowledge of the climate is not enough to allow a reconstruction of the past vegetation cover The effects of burning and of a more prolific fauna have also to be taken into account Ecologists and archæologists working together in the field are beginning to produce fairly reliable pictures of ancient landscapes, and R. O Whyte, in his contribution on south-east Asia, sees much promise in this type of co-operative research

South-west Asia is in many ways the most important of the regions and at the same time it produces the greatest difficulties in comprehension because of the mass of information available from widely scattered sites and conflicting interpretations of evidence Whyte's review is very stimulating but not at all easy to digest Egypt is of its nature simpler, and the material presented by G Hamdan will be more familiar to many readers V A Kovda's survey of the Russian plains, the Caucasus and Central Asia (plus a few pages on irrigation in China) naturally lays great stress on the revolutionary effects of introducing socialist methods of production to the steppe The scale of operations is indeed impressive Kovda notes the steady increase in the frequency of *sukhovei*, dry dusty winds, but asserts that their effects will be mitigated by new forests and irrigation projects which, he says, are expected to increase precipitation

J Despois, writing on North Africa, agrees with Butzer that there is no good evidence that the climate there was much more favourable to farming in the Roman period than in later times The decline in agriculture can mainly be attributed to eleventh-century and later invasions of Bedouin Arabs from the east Even their destructiveness seems to have been far exceeded by those other nomadic herdsmen, the Mongols, who descended on western Asia two centuries later From both, recovery was slow, and in Cyrenaica and parts of Iraq and Iran is still incomplete

Nomadism is a rational response to those seasonal and year-to-year variations in grazing and surface water typical of arid regions R F Logan describes flocks in the United States being driven in double-decker trucks to summer grazing in upland meadows under Forest Service permits Everywhere some State control of nomadism seems to be inevitable Although, as Th Monod and Ch Toupet note in the Saharan region, an irreversible process of "sedenterization" has set in since pacification, progress in this direction is likely to be too slow to satisfy administrators and conservationists

Innovations bring old problems Perennial irrigation can lead to salt accumulation and waterlogging, as in the Punjab, and to bilharzia and other diseases Improved water supplies from deep wells can accentuate overgrazing The balance is delicate in arid lands and the regulating mechanism must work efficiently or disaster comes swiftly. This seems to be the main lesson to be learned from the past

For the future, the possibilities of industry based on local minerals, with space-cooling and a sunny climate to attract labour, are becoming apparent from recent developments in Arizona and Central Asia The process of urbanization is not new to the arid lands, it probably began there, and may well go further there than anywhere else in the world

OBITUARIES

Dr. B. L. Goodlet, O B.E

THE death occurred on October 27 of Dr Brian Laidlaw Goodlet, deputy chairman of the Brush Electrical Engineering Co , and, until recently, its managing director

Brian Goodlet was born in St Petersburg in 1903 of British parents who had settled in Russia in the service of the Government, and was educated at the Imperial School in St Petersburg He escaped from Russia during the Revolution and received his further training with Vickers, Ltd , and Metropolitan-Vickers, first at the Attercliffe Works, Sheffield, studying in the Applied Science Department of the University of Sheffield, where he gained the associateship in electrical engineering, and then as a special trainee in the Trafford Park Works In 1924 he was appointed to the staff in charge of the first High-voltage Laboratory, and there he introduced to the Company high-frequency and impulse voltage testing of electrical products, and made important contributions to the study of transmission and bushing insulators, during which time he designed the second High-voltage Laboratory equipped for a million volts He also designed the very small high-voltage generator which the Metropolitan-Vickers Co gave to the Cavendish Laboratory to assist me in the first attempts to accelerate particles to very high energy for transmutation experiments, and then designed the special high-voltage transformer of extremely small dimensions which was used by Cockcroft and Walton in their 1932 experiments There were no other high-voltage transformers in those days which could have fitted into the small rooms of the Cavendish Laboratory, and we owe Goodlet a great debt for these expert designs without them Britain might not have been ahead of the large American laboratories

It was through his contacts with the Cavendish Laboratory that he decided to take the Engineering Tripos in Cambridge, leaving Manchester at the age of twenty-seven with a generous grant from the Company On his return to Trafford Park he made a detailed study of extra high-voltage turbo-alternators, and also wrote his classic paper on lightning

In 1937 Goodlet was appointed to the chair of electrical engineering in Cape Town, but he returned to Britain in 1939 to take up the chair in Birmingham He offered his services to the Admiralty, but, because of his former connexion with Russia, he was not accepted, so he applied to return to the still vacant chair in South Africa, where he immediately joined the South African naval work on the degaussing of ships in Cape Town Harbour, ultimately gaining the rank of commander in the South African Navy After a short time he was sent to England to work with the British Admiralty as chief scientist at Rosyth, where he made distinguished contributions to work on underwater explosions, before joining the Far East Naval Task Force in Ceylon under Lord Mountbatten He was made O B E for his war services In 1946 he returned to Cape Town, where he built up a vigorous electrical engineering department with almost pitiable funds, gathering around him several engineers from the Metropolitan-Vickers Co and starting a lively research school, but this had scarcely begun to bear fruit when he returned to England again in 1950, this time as deputy chief engineer of the Atomic Energy Establishment at Harwell His text-book on basic electrotechnics—the result of his post-war work in South Africa—has become well established in British universities for second- and third-year honours engineering students

Goodlet began in Harwell with a small team, including Mr R V Moore, to investigate in detail the feasibility of a power-producing nuclear reactor system, referred to as *Pippa*, using natural uranium The team selected graphite as moderator, carbon dioxide as coolant gas and a vertical arrangement of fuel rods, and by 1952 all the main features of the design had been established it was then handed over to the Production Division to produce Calder Hall It is a tribute to Goodlet's engineering judgment that no major changes of design were necessary (His paper, "Nuclear Reactors for Power Generation", to the Institution of Mechanical Engineers, was awarded the Thomas Hawksley Gold Medal)

During 1952–56 he was the chairman of the Naval Education Advisory Committee of the Admiralty the Director of the Naval Education Service advises me that he made an ideal chairman and was greatly respected by his colleagues During Goodlet's period of office, the Committee advised on a number of important matters, including cadet entry into the Royal Navy, officer training, the technical training of junior ratings, the conditions of service of civilian teaching staff at the Royal Naval Colleges, the rehabilitation of the Dockyard Technical Colleges and the organization of facilities for informing the Service of modern developments in science and technology. His untiring interest and wise counsel in all aspects of naval education were of the utmost value to the Director of the Naval Education Service

By 1956, Goodlet felt that his work at the Atomic Energy Research Establishment was finished, and he joined the Brush Electrical Co , Loughborough, as chief engineer and director, later becoming its managing director Mr G B R Feilden tells me that Goodlet was confronted by a series of major breakdowns of 30-MW double-rotation turbines which had been designed before Goodlet joined the Company The breakdowns were caused by vibration, and the solution to the problem required the evolution of entirely new measuring techniques Goodlet was responsible for solving this problem, which was fortunately achieved successfully, largely due to his own perseverance, shortly before his death He submitted his published work to Cambridge and was awarded the Sc D in 1958

Perseverance and thoroughness characterized all his work like the great American engineer, Charles Proteus Steinmetz, he was never satisfied until he understood the fundamentals of any problem which confronted him, and he was fondly nicknamed 'Prot' by his closest friends because of this similarity He invariably wrote out the basic facts and deduced the solution in beautiful handwriting, and his notebooks were a joy to peruse His perseverance was equally manifest in his hobbies, and he enjoyed going up Table Mountain the hardest way He was extremely interested in military strategy and it was fascinating to hear him quote Napoleon's campaigns, he even wrote a mathematical paper on the ballistics of weapons used in classical times I was present when Rutherford, returning from the British Association meeting in South Africa, recited the exploits of Cetywayo, Goodlet, to Rutherford's great delight, continued the story with intimate details of the part played by the Zulu's lieutenants

Goodlet is survived by a widow, two sons, and two daughters T E ALLIBONE

Dr A K. Das

INDIA lost a meteorologist of note and a leading astronomer of this century with the death on February 18, 1961, of Anil Kumar Das. He was best known for his work at Kodaikanal Astrophysical Observatory, of which he was the head for fourteen years At the time of his death, however, he was acting temporarily as director of the Nazamiah Observatory, Hyderabad, and as professor of astronomy at Osmania University But although best known for his astrophysical researches, Dr Das published a number of papers on purely meteorological topics, mainly during the early part of his thirty-years service in the India Meteorological Department

After completing his education to postgraduate level in India, Das continued his studies in Paris under Fabry and later also worked with Max Born and Augenheister He returned to India in 1930 to commence his meteorological work, but in 1934 he went to England to study the temperature of the Sun by spectro-photographic means at the Solar Physics Observatory, Cambridge This virtually marks the beginning of his career in astronomy His many papers on solar physics thereafter appeared at regular intervals almost up to the date of his death

Das had the intuitive foresight, great energy and determination of the great research worker, but he was also an administrator of considerable ability Indeed, his greatest achievements probably lie in the improvements he introduced at Kodaikanal, by the installation of new equipment and the initiation of new fields of research Largely thanks to Das, this Observatory is now carrying out researches and making observations, using the finest equipment, in many branches of geophysics and solar physics It is a pity that he could not live long enough to fulfil his last ambition to work with his new instruments during the last years of his life

NEWS and VIEWS

Botany in University College, Dublin

Prof J Doyle

PROF JOSEPH DOYLE has retired from the chair of botany in University College, Dublin, after nearly fifty years service He entered the College on a mathematical scholarship, later he became interested in biology through the pathway of medicine Following a period of postgraduate research, part of which was spent in Germany, he was appointed assistant in biology in 1913, at this time, he and two others comprised the staff of the Biology Department In 1924 he was appointed professor of botany, and undertook the development of the first Department of Botany in the College His main research interest is represented by a long series of papers on conifer embryology, on which subject he is internationally recognized as an authority He was awarded the Boyle Medal of the Royal Dublin Society in recognition of this work The degree of D Sc was conferred on him in 1930 At the Dublin meeting of the British Association for the Advancement of Science in 1957, he was president of Section K (Botany) In addition to developing the Department of Botany, Prof Doyle rendered distinguished administrative service to his College As dean of the Faculty of Science he showed considerable organizing power, for many years he was a member of the Governing Body of the College and of its Finance Committee He has helped greatly in furthering the scientific and cultural life of Dublin He is a member of the Council of the Royal Dublin Society, secretary of the Royal Irish Academy, chairman of the Praegar Committee for Field Natural History, and a trustee of the National Library of Ireland Recently he has been actively engaged in planning new Science Buildings for University College, Dublin His many interests will ensure for him rewarding occupation in his retirement

Prof Phyllis M Clinch

DR PHYLLIS M CLINCH has been appointed to succeed Prof J Doyle Dr Clinch, in fact, majored in chemistry in University College, Dublin, with first-class honours and first place at her primary degree, but, botany being her second subject, she took an immediate interest in plant biochemistry and her earlier research was done in the Department of Botany on problems of seasonal metabolic changes in conifers In this and in all her subsequent work her early intensive training in basic chemistry proved a most valuable asset After a period of study under Prof V H Blackman in the Imperial College and Prof Guilliermond in Paris, she was appointed senior research assistant in plant virus diseases in the Department of Plant Pathology, University College, Dublin Here she played a major part in the team that produced so much important work on plant viruses, especially the analyses of viruses affecting the potato plant The value of the work from this Irish School is too well known to need comment here, suffice it to say that Dr Clinch's share in it has gained her a well-merited international reputation in the plant virus world In 1950 she accepted an invitation to join the staff of the Botany Department, University College, as senior lecturer with the primary purpose of developing courses and research in plant biochemistry and physiology along modern lines The very successful organization of this entailed, unfortunately, a temporary break in her work on viruses The break, however, was only temporary, and in recent years she has initiated a programme of research into the biochemical and physiological effects of virus infection on the metabolism of the infected plants themselves It is to be hoped that the administrative and other duties which will now naturally fall on her as head of a department will not unduly hamper progress in this promising line of research

Control of Government Expenditure on Research and Development

IN opening a debate on November 30 when the House of Commons was asked to take note of the First, Second and Third Reports from the Committee of Public Accounts in the Session 1960–61 and of the Special Report from that Committee, Mr. H. Wilson referred to the centenary of the establishment of the Committee in April 1861 and to the steady development of its work. The debate covered a fairly wide field, but the two chief points of scientific interest are to be found in the reply of the Financial Secretary to the Treasury, Sir Edward Boyle. Sir Edward, referring to research and development practice, endorsed the Treasury Minute that it is Government practice to rely largely on private industry when it is a matter of design studies for complicated new weapons and equipment, subject to the checks which Government establishments can operate, and that research, development and production are integral parts of a continuous process to which the Ministry of Aviation's research establishments contribute by virtue of their specialized knowledge and facilities. Sir Edward also said that the major part of the Atomic Energy Authority's net cost of operations—nearly £60 million in 1959–60—represents research and development effort in both the civil and military fields, and to publish the civil figures alone would make it easy to estimate the level of military research. Decisions on all matters concerned with the disclosure of information are taken after regular periodical reviews, and the importance of this issue to the Public Accounts Committee was realized. In principle, the Authority hoped to recover its research and development expenditure on civil reactor systems.

Medical Men in Britain

IN a debate in the House of Lords on November 29 on the shortage of medical men, Lord Taylor stressed the difficulty which non-teaching hospitals in Britain are experiencing in filling appointments. In replying for the Government, Lord Newton said that after reviewing the data and calculations of the Willink report, the Government is satisfied that the prospective demand for medical services will justify a rise in the university intake of pre-clinical students from Great Britain of 10 per cent above the 1,760 recommended by the Willink Committee. The intake in July 1961 was 1,788. The University Grants Committee has been asked to consider with the universities the implications of the Government's conclusion. Steps are being taken to improve the statistical information so far as reasonably possible. Lord Newton said that the Government intends to watch the figures constantly, including those of output from the medical schools, rather than attempt to make firm estimates at wide intervals of time. Lord Taylor had asserted that the shortage is now showing itself in the teaching hospitals also, and that the hospital service in Britain would have collapsed but for the influx of some 3,000–4,000 junior doctors from India and Pakistan. Lord Newton admitted that in March 1960 more than one-third of the posts in the middle and lower grades were occupied by doctors born outside Britain, but he emphasized the value of these doctors and the debt to their services. He said that in 1960 the average number of patients on a doctor's list was 2,287, about 150 fewer than it was in 1952, and that the improvement of the distribution of doctors was of special concern to the Medical Practices Committee constituted under the National Health Service Act.

Accelerators for Low-energy Nuclear Physics

RECENT advances in the theoretical description of the atomic nucleus, together with recent design improvements in cyclotrons and Van de Graaff accelerators have stimulated a special U.S. National Science Foundation programme for establishing and improving low-energy nuclear physics research facilities. The theoretical advances have resulted in a need for refined measurements of energy-levels, spin assignments, and other characteristics of the nucleus so that the synthesis of present theoretical models can be further advanced. Many of these refined measurements are now possible through extension of the range of Van de Graaff accelerators giving particles with energies of up to 20 MeV., and improvements in cyclotron design to permit well-controlled beams up to 40 MeV. Until about five years ago Van de Graaff accelerators were restricted to energies less than 8 MeV. Recently, the Foundation has made a group of six grants, totalling 4,161,500 dollars, in furtherance of the new programme. These six accelerators are expected to play an important part in the nation's effort in nuclear structure physics. Grants made so far in this special programme are as follows: University of Chicago, 296,700 dollars for a 4-MeV. Van de Graaff machine to be used by Dr. S. K. Allison and his Group; Michigan State University, 700,000 dollars toward a 40-MeV. cyclotron for the use of Dr. Henry G. Blosser's research team; University of Pittsburgh, 977,600 dollars toward an 18-MeV. three-stage Van de Graaff machine for research under the direction of Dr. Bernard L. Cohen; University of Washington (Seattle), 1,240,000 dollars toward a 22-MeV. three-stage Van de Graaff machine for the Physics Department, of which Dr. Ronald Geballe is executive officer; Ohio State University, 499,200 dollars for a 5·5-MeV. Van de Graaff machine for the Department of Dr. H. H. Nielsen; State University of Iowa (Iowa City), 498,000 dollars for a 5·5-MeV. Van de Graaff machine for the Department under Dr. James A. Van Allen.

The Royal Commission for the Exhibition of 1851

THE eleventh report of the Commissioners for the Exhibition of 1851 covers the activities of the Royal Commission since its tenth report was issued in May 1951 (Pp. 32. (Cmnd. 1502.) London: H.M.S.O., 1961. 2*s*. 6*d*. net). The general pattern of the Science Research Scholarships has remained unchanged, but the list of universities invited to participate has been extended and the value of the awards increased to £550 a year for Overseas Scholars and £800 a year for senior students, exclusive of allowances. In 1958 the National Research Council of Canada offered to each 1851 Scholar from Canada a bonus of £250 a year from its own funds, which has been particularly useful to married Scholars. Similar arrangements have been made, with various qualifications, by authorities in Australia, South Africa, India, Pakistan and New Zealand. Since 1952 the Commission has co-operated with the Council of the Royal Society in the administration of the Rutherford Scholarship. The value of the Postgraduate Scholarship in Naval Architecture was in 1958 increased to £600 a year. In view of the re-allocation of so much of the property on the Kensington Gore Estate in 1956, it was agreed with the Imperial College of Science and Technology and Government departments concerned to arrange a new lease to the College for 999 years from midsummer 1956 at a rental commencing at £5,000 and rising over ten years to £25,000 a year

The Commission's office at 1 Lowther Gardens provides accommodation also for the London headquarters of the British School at Rome, to which the Commission now contributes £8,000 a year, and for the Institute of Physics and the Physical Society Of the expenditure of £324,759 during the ten years January 1, 1951–December 31, 1960, £244,822 was on direct educational grants A new *Record of the Science Research Scholars of the Royal Commission for the Exhibition of 1851, 1891–1960,* has now been compiled, and it may be noted that of the 905 Scholars, 99, including 34 from overseas, became Fellows of the Royal Society, of which two were elected president, eight won Nobel Prizes (Pp iv + 107 London Royal Commission for the Exhibition of 1851, 1961 12*s* 6*d*) The *Record* lists separately Science Research Scholars appointed during 1891–1921, Overseas Scholars appointed since 1922 and Senior Students appointed since 1922 There are indexes to Scholars and to the Institutions from which they came

Experimental Eye Research

THE scientific literature on the eye and vision is dispersed in journals representing many different disciplines, and visual scientists have for long deplored the fact that they had no journal of their own Now they are to have at least two For the appearance last June of *Vision Research* (Pergamon Press) (see *Nature,* 191, 650, 1961) is followed by the present debut of *Experimental Eye Research* (Academic Press). Congratulations are due to Academic Press for the fine quality of *Experimental Eye Research,* the first number of which appeared in September (1, No 1; September 1961 Pp 97 Published quarterly Vol 1, approx 400 pages (London: Academic Press, Inc (London), Ltd ; New York: Academic Press, Inc , 1961) 115*s* , 16 dollars) The object of this quarterly journal is the publication (in English) of original papers on the anatomy, physiology, biochemistry and biophysics of the eye "Contributions on such subjects as the production and circulation of ocular fluids, the fine structure, biochemistry, biophysics and metabolism of the eye tissues, the photochemical processes related to visual function, and the neuromuscular mechanisms in the control of eye movements will be preferred " The editors-in-chief are Dr E A Balazs, of Harvard Medical School, and Dr Hugh Davson, of University College, London They are supported by a group of leading workers forming an editorial board of five and an advisory board of nine A study of the first issue reveals a high standard of editorial policy and also confirms the initial impression that the main interests of the publication are the minute anatomy and vegetative physiology of the eye Since the interests of the 'rival' publication, *Vision Research,* are centred more on the physiology of vision, there is less overlap in the scopes of the two journals than might appear

Engineering and Television

Two publications of the British Broadcasting Corporation issued to mark the twenty-fifth anniversary of B B C Television direct particular attention to the work done by its engineering division during the period under review The first, *Twenty-five Years of B B C Television,* is one of its periodic *Monographs* and has been prepared by one of the original members of the B B C , Sir Harold Bishop, now director of engineering (No. 39 Pp 41 (14 plates) London British Broadcasting Corporation, 1961 5*s*) After a survey of the events and developments which led to the start of the B B C 's high-definition television service, the monograph describes the main engineering developments during the past quarter of a century Particular attention is directed to those techniques which have been originated by the B B C , or which are utilized in a specially noteworthy manner in the services of the B B C. There is also a brief review of the B B C 's contributions to probable future developments, including colour television and a change of standards The second publication, *B B C Television a British Engineering Achievement,* is written in a more popular style, and gives a narrative account of how television works, the early growth of the services and what engineering services and techniques are involved to bring television into the home The brochure is well written, with good illustrations and, like so many B B C publications, is remarkably cheap (Second edition, revised Published on the 25th Anniversary of B B C Television Pp 64 London: British Broadcasting Corporation, 1961 3*s* 6*d*) It should find its way to bookstalls as well as libraries in schools and other places

Astronomical and Nautical Almanacs

Two ephemerides have recently been published for the year 1962, one by the U S Government and the other by the Indian Government. *The American Ephemeris and Nautical Almanac* is unchanged with regard to the presentation of material (Pp vii + 514 Washington, D C Government Printing Office, 1960 4 dollars) *The Indian Ephemeris and Nautical Almanac* (Pp xxviii + 460 Delhi Manager of Publications. 1961 Rs 14 00, 22*s*) is closely similar to the American *Ephemeris,* though more restricted in scope, but in addition contains a section on the Indian Calendar. The 1962 edition contains four new sections: (1) ephemeris for physical observations of the Sun; (2) ephemeris for physical observations of the Moon, (3) centre of mass of the solar system, and (4) local circumstances of occultations of bright stars and planets visible in India

Technical Publications of the Oak Ridge National Laboratory

THE publication *ORNL* 61-6-27 contains a list of papers published in journals and presented at meetings, reports issued, and theses completed, during 1960, by the members of the staff of the Oak Ridge National Laboratory, Oak Ridge, Tennessee (Pp v + 107 Oak Ridge, Tennessee Oak Ridge National Laboratory, 1961) Reprints of many of the articles can be obtained on request either from the Laboratory, or of papers presented at scientific meetings from the authors concerned There is an author index, and the various articles are grouped within the sections according to subject, biology, chemistry, physics, etc The prices of the *ORNL* reports are given, and the reports, except those indicated as 'not for sale'. can be obtained through the Office of Technical Services, Department of Commerce, Washington 25, D C

National Conference of Standards Laboratories

To help meet the needs of science and industry for improved uniformity and greater precision in calibration and measurements in all areas of the physical sciences, engineering and technology, a new organization—the National Conference of Standards Laboratories—was established on September 15, 1961, by representatives concerned with standards activities in Government, industry, education, and professional societies of the United States A major activity of the National Conference will be to arrange a continuing series of standards laboratory conferences The General Committee, headed by Lloyd B Wilson, of the Sperry Gyroscope Co , has arranged for the first conference in this series to be held during August 1962 at the National Bureau of Standards Boulder Laboratories, Boulder, Colorado Another major activity being considered is the establishment of a voluntary system of measurement agreement checks to demonstrate competence and continued uniformity among standards laboratories Further information can be obtained from Dr H W Lance, Electronics Calibration Center, Boulder Laboratories, National Bureau of Standards, Boulder, Colorado.

Conference on Measurement and Control Technology

The Society of Instrument Technology and the Royal Dutch Institute of Engineers are organizing a joint conference to be held during April 10–13, 1962, in Amsterdam The programme is being arranged to encourage discussion and exchange of information on the present state and future trends of measurement and control technology in Britain and Holland Six technical papers will be presented and discussed covering new measurement methods such as direct reading spectrography, X-ray fluorescence chromatography and optical measuring techniques, descriptions of working automation projects in the biscuit industry and sinking mine shafts, and control in manufacturing industry While most of the places will be reserved for members of the Society of Instrument Technology, it may be possible to entertain a few applications from non-members Further information can be obtained from Mr I V Idelson, Mullard Equipment, Ltd, Manor Royal, Crawley, Sussex

University News : Birmingham

The following appointments have recently been announced Dr J S Brimacombe, to be lecturer in the Department of Chemistry, Dr D E N Davies, to be lecturer in the Department of Electrical Engineering, Dr F Rieband, to be lecturer in the Department of Mechanical Engineering, E D R Shearman, to be senior lecturer in electromagnetism in the Department of Electrical Engineering

Leeds

In a statement to a meeting of the Court of the University of Leeds on November 15, when the annual report was presented, the vice-chancellor, Sir Charles Morris, referring to the increase in the number of students by 1,400 in five years, said that in the past year it had increased by 386 to 5,175, and it was probable that this order of increase would continue during the forthcoming quinquennium and that the student population in 1966 would be 6,900 The building programme was based on an increase of this order, but there was some risk that the provision of residential accommodation might seriously fall behind needs in the immediate future The vice-chancellor also referred at some length to the new courses which the University was offering leading to an honours degree covering study in depth in two of the traditional subjects These courses were meeting with immediate response, and twenty-one students were expected to graduate this year in the 'combined' courses in arts, the most popular combinations so far being economics and history, English and history, geography and history, and psychology and sociology The Science Faculty was starting such courses next October and a director of combined studies was being appointed to guide the students following these courses and advise on combinations of subjects While he did not think the 'special honours' courses would disappear or lose prestige, he thought it would be increasingly accepted that at the standard of first degree at honours-level, two subjects could effectively be studied together in depth

Sussex

The following appointments have been made Dr D B Scott, at present reader in mathematics at King's College, London, to be professor of mathematics, Dr. E R A Peeling, at present senior lecturer in chemistry in the University of Leicester, to be senior lecturer in chemistry

Announcements

Sir Harry Melville, secretary of the Department of Scientific and Industrial Research, has been made a member of the Council for Scientific and Industrial Research in recognition of his "notable services to D S I R " The appointment is personal to Sir Harry and does not mean that future secretaries of the Department of Scientific and Industrial Research will automatically become members of the Research Council

A symposium on the "Methodology of Plant Eco-Physiology" will be held in the Botanical Institute, 5 rue Auguste Broussonnet, Montpellier, France, during April 7–12, 1962 Further information can be obtained from Dr. F. E Eckardt, Institut de Botanique, Montpellier, France

The Department of Physics and Astronomy of the Ohio State University is organizing a symposium on "Molecular Structure and Spectroscopy", which is to be held in the University during June 11–15 Further information can be obtained from Prof R A Oetjen, Department of Physics and Astronomy, Ohio State University 174 West 18th Avenue, Columbus 10, Ohio

Due to a change in date of the meeting of the International Pharmaceutical Federation, which will be held in Vienna during September 1–24, 1962, the third British Congress on the History of Medicine and Pharmacy will be held in London during September 27–28, 1962 The subject of the Congress will be "The History of British Hospitals" Further information can be obtained from Dr F N L Poynter, Wellcome Historical Medical Library, Euston Road, London, N W 1.

Erratum We regret to find that, in the article entitled "Action of Radiation on Synthesis of Deoxyribonucleic Acid in Normal and Tumour Strain Cells" (*Nature*, December 9, p 944), a line has been omitted and another duplicated In column 2, p 944, lines 15 and 16 should read " a decrease from the consequent depletion of the cell population However, as Painter and . " The present line 16 is a repetition of line 13

INTERPRETATION OF GEOPHYSICAL SURVEYS

RECENT improvements in geophysical instruments have not simplified interpretation of the data obtained by using them Indeed, their greater speed and higher accuracy increase the data to be analysed and foster attempts to interpret in finer detail Assessment of factors controlling the reasonable limits of interpretation was the main aim of a Geophysical Discussion of the Royal Astronomical Society, held in association with, and at the rooms of, the Geological Society on October 27 Introducing the four invited speakers, the chairman, Dr. W Bullerwell (Geological Survey), remarked that geophysical interpretation is usually tested by subsequent geological exploration, thus it was appropriate that discussion about interpretation should take place among geologists and benefit from their comment

In opening the discussion, Prof J M Bruckshaw (Imperial College of Science and Technology, London) reviewed the treatment of gravity and magnetic survey data, where interpretations aim to deduce sub-surface mass distributions accounting for observed surface fields Fundamental difficulties are ambiguity and lack of resolution Ambiguity reflects dependence of the gravity anomaly on several factors, including form, size, depth and density contrast When all these factors concerning a buried mass are known, it is possible to predict uniquely the effect on gravity at any point on the surface, but when interpreting a gravity profile recorded in a new area, the factors cannot be evaluated individually, and possible permutations allow many solutions consistent with the profile Only geological control can limit the inherent ambiguities Lack of resolution was illustrated by indicating that the interpreter cannot distinguish a point mass from a cube or sphere, since all produce similar gravity profiles Depth to centre, however, can be computed with reasonable accuracy and an estimate of size is obtainable from the maximum of the anomaly, though it depends in turn on an estimate of density contrast

Various numerical methods of analysis have been proposed, but Prof. Bruckshaw stressed that mathematical transformations cannot overcome limitations inherent in the original data, while subjective bias may be introduced in the process As a preliminary step, it is usual to isolate local anomalies thought to represent shallow geological structures by removing a regional background corresponding to smooth average variations Only rarely, however, can the regional be assigned geological significance, and the smoothed form assumed varies between different interpreters Attention has been given to the second vertical derivative of gravity following claims of higher resolution from a fourth-power relation with depth as compared with the normal square law, and correspondence between zero contours of second derivative and vertical density boundaries Unfortunately, precise evaluation of second derivatives requires continuous information whereas field observations are made at a series of discrete points One process of analysis depends on the subjective drawing of smooth curves through available points Alternatively, an interpolation formula may be applied, but developed formulæ give different solutions depending on size and form of primary grid Final stages depend on comparisons with model curves, and it is important to derive these using the same grid In reconnaissance of new areas, such methods are rarely warranted No amount of mathematical analysis can remedy insufficient geological control, and if only geophysical data are available, interpretation always remains ambiguous This was demonstrated recently in an example published by P E Jacobson, of the Creole Petroleum Co , showing differences between two independent interpretations of a magnetic survey in eastern Venezuela However, if good geological control is available and physical properties of the geological formations have been extensively studied, as in parts of England, some difficulties can be resolved and confident estimates advanced

Dr M H P Bott (University of Durham) agreed that gravity and magnetic data are ambiguous, but felt that useful conclusions can generally be salvaged from the sea of uncertainty by applying simplifying assumptions legitimately drawn from geological knowledge of similar environments The practical limit of interpretation is frequently determined by how far such reasonable assumptions permit assessment of background and isolation of the interesting anomaly from other disturbances Once the anomaly has been isolated, total mass can be accurately evaluated by areal integration of the gravity contours Russian work, recently developed further by Dr R A Smith, shows that if only a few conditions are satisfied a unique solution may be possible As an example, if an anomaly arises at a single interface across which the density contrast is constant and known, then the shape of the interface can be interpreted directly Usually the limiting conditions are not accurately known but can be expected to lie within a certain range, and this information permits use of an uncertainty principle through the inequality theorems of Bullard and Cooper, later extended by Bott and Smith Minimum and maximum values for depth to the source of the anomaly can be obtained Limiting depth estimates can be derived also from second and third horizontal derivatives of the gravity anomaly, through formulæ of Dr R A Smith relating maximum derivative and maximum depth The limiting case, corresponding to a symmetrical truncated wedge-shaped body with each edge contributing equally to the derivative, can be modified for the situation where one edge is distant from the point of observation, as for measurements at the margin of an extensive body Dr Bott showed how, using this method, he had analysed profiles across the margin of the Weardale anomaly for an estimate of depth to the top surface of the postulated Weardale granite, afterwards proved (at a depth of 1,281 ft) in a deep borehole at Rookhope, Co Durham Using maxima in second and third horizontal derivatives calculated from closely spaced observations by gravity meter and assuming density contrast of 0·2 gm /cm.^{3}, analysis had shown that the top of the postulated granite must lie at less than 3,500 ft beneath Weardale It is difficult to measure gradient maxima sufficiently accurately with a gravity meter, since an average over a base-line and not a point-value is observed. Dr. Bott believes that the torsion-balance, little used recently, might be used advantageously.

Similar methods often prove satisfactory for deciding between alternative geological possibilities, as in distinguishing gravity lows over sedimentary basins from those due to granites. In the former case the boundaries of the lighter sediments slope in towards the centre of the anomaly, whereas the granite margins slope out at depth. Different amplitude ratios between derivative maximum and minimum flanking the anomaly are detectable, and contrasting results from gravity traverses crossing the margins of the Cheshire Basin and the Dartmoor Granite were displayed. Finally, useful results can be derived from comparisons with models, since modern digital computers will check quite speedily whether a postulated geological structure would produce the profile observed or whether marked divergences necessitate a new hypothesis. Dr. Bott concluded by saying that, applied to analyse magnetic data, these methods encounter added difficulties due to variations in direction of permanent magnetization.

Mr. G. Tait (Iraq Petroleum Co.) contributed a paper outlining the geophysicist's views on interpretation of seismic surveys. He remarked that recent instrumental developments aim at producing a greatly simplified presentation of results in the hope that by transforming a series of impulses into a variable density profile the main features of the geological structure may be comprehended at a glance. No method of presentation, however, alters the fact that the behaviour of the seismic wave depends on elastic constants in the rock formations concerned and progress or difficulties in interpretation relate to whether and where variations in these constants occur. It is not always possible to predict from lithology, for seismic velocities in adjacent sandstones and limestones can be identical. Local velocity control is doubly important, because velocity discontinuities may not correlate directly with stratigraphic interfaces and because travel-time and velocity have equal weight in seismic determination of depth. Satisfactory velocity data can be obtained from well-shooting or by recording velocity logs in deep boreholes, but in virgin areas, where information must come from surface shots, available values may be inadequate. Accurate velocities can help when distinguishing between multiple reflexions and deep reflectors from curvatures in the moveout or by recognizing anomalous dips.

Several of these and other complications which the interpreter must disentangle were clearly demonstrated from oil exploration surveys by the Iraq Petroleum Co. One slide showed how tangential distortion against high-speed beds can simulate the indications of a natural structure. Importance of spread-length was apparent in the same example, since curvatures which could not be identified on a short spread became clearly visible at 12,000 ft. Records of a noise-spread indicated that alignments in background may confuse with weak reflexions. Profiles shot in the foothills of Iraq demonstrated both the problems and the importance of identifying multiple reflexions and diffraction cross-overs which may have amplitudes greater than those of the geologically significant events. Lower-amplitude contrast between events in a profile across the main producing oilfield of Iraq made it appear somewhat of an anticlimax, though containing important information. Mr. Tait's evidence made clear that, in dealing with seismic records, the interpreter must continuously bear in mind natural conditions under which the survey has been performed, velocity data available, instrument lay-out and complications which may have confused the records with multiple reflexions and diffraction effects.

Mr. A. N. Thomas (British Petroleum Co.) discussing geological factors in the planning and interpretation of seismic surveys, stressed the need for close co-ordination of geological and geophysical information. His first example, taken from the Po Valley, showed seismic reflexions on a phantom horizon to which geological information had been added, seismic evidence controlling the section as to fault zones and dips, while stratigraphical detail came from boreholes. Following examples came from south-west Iran, where initial interpretation difficulties with seismic refraction surveys were resolved when stratigraphical considerations correlated highest velocity with Middle Cretaceous Rudist limestone, not with the massive Asmari limestone 2,000–3,000 ft above. Refraction arcs in the Lali Plain, starting from positions determined by surface geological mapping, directed attention progressively southwards to prove concealed Asmari limestone structures. In other British Petroleum Co. surveys across Agha Jari and Lali, surface dip observations by geologists in an area of disharmonic folding gave valuable checks on geophysical evidence about elevation of a concealed crest. In exchange, structural interpretation of the surface geological maps was aided by the geophysical information. Evidence from Iran showed that, by producing regional isopach and facies maps, the geologist can illuminate seismic interpretation wherever such variations control velocity or ability to act as a refractor.

The bearing of velocity anomalies on seismic interpretation was next considered using an example by D. C. Skeels from a Devonian reef oilfield in West Canada. Reflexion times at boreholes to the Lower Cretaceous gave a velocity map used for controlling the seismic data, and the final seismic depth-map agreed with later sub-surface information more closely than an earlier map based on reflexion times only. In more complicated conditions accompanying Reef limestones in Western Alberta, structure contour maps and seismic isochron maps may show different relationships on successive horizons. Causes are sometimes difficult to assess, but it is clear that seismic evidence must be checked against drilling data at all available positions and levels. Difficulties in correlating reflexion pulses with specific geological formations were illustrated in results obtained near Calgary by Dr. T. C. Richards, in which corresponding seismic peaks and troughs could be seen to change stratigraphic horizon in different parts of the area. The sections also showed how ideas about the structure of the area changed as various stages of drilling, seismic survey and further drilling were completed. This analysis indicated the tendency of the seismic interpretation to smooth out complications and inability to locate with certainty the top of the Palæozoic, which is the most important lithological break.

Mr. Thomas concluded by saying that too much should not be expected from a seismic survey. It cannot eliminate the need for sound geological investigation; both lines of approach are necessary. The seismic method cannot give a complete picture of sub-surface conditions in areas of complicated structure, and geologists should realize the limitations imposed by the nature of the method.

Opening the meeting for general discussion, Dr Bullerwell recalled a remark of Prof Bruckshaw that potential theory has been known a very long time and that in many fields interpretation shows no fundamental advance over the past fifteen years Noting that during this period there has been increased use of systems like the airborne magnetometer for recording continuous profiles, he asked whether these removed some of the subjective elements mentioned Prof Bruckshaw replied that the subjective element remains in spite of such developments, due to the gaps between profiles and uncertainties in completing contours Though coverage is improved, it is never complete Dr W Domzalski felt that some views expressed had been unduly pessimistic Even though interpretations might prove quantitatively in error, qualitative results obtained following an imaginative approach often lead to new discoveries For reasonable success in interpretation it is also important to choose the geophysical method most suited to the geological problem Even where no control information to guide the interpretation is available, the possible results may justify geophysical work as the most economical means of preliminary reconnaissance

On the question of economics, Dr Bullerwell asked how soon during a survey should the results be tested by drilling Mr. N L Falcon said that satisfactory exploration implies a balanced programme combining geology, geophysics and drilling It is desirable to establish control, pursue the investigation comprehensively and not anticipate conclusions on the basis of too few results, but geophysical interpretation remains speculative until the key localities are drilled Dr T C Richards said that geophysical experiences in Canada emphasize the importance of early drilling control A quantitative approach is essential throughout and second-derivative gravity maps have proved unreliable for this Seismic methods must be introduced at a very early stage and have adequate geological and drilling control, especially in the Reef field, to overcome difficulties due to facies changes Otherwise, occurrences of Reef limestone in limestone or local velocity anomalies, as at Swan Hills, Alberta, would not be recognized

In closing the meeting the chairman remarked that personal experience often decides for one interpretation method rather than another Perhaps a real advance during the past fifteen years is represented by pooling of experience through free discussion and improved publication of geophysical results There is certainly a clear recognition of fundamental problems W BULLERWELL

TWELFTH INTERNATIONAL ASTRONAUTICAL CONGRESS

THE International Astronautical Congress is an annual meeting of the interplanetary societies of the world Societies take it in turn to act as host, and the recent meeting, during October 1–7, in Washington, was the first occasion that the meeting had been held on the American continent Next year's conference was fixed for Sofia, Bulgaria, it having been held in Stockholm last year and London in 1959 Of the 750 people registered, some 300 came from outside the United States The president of the International Astronautical Congress this year was Academician L I Sedov, of the U S S R , and for the forthcoming year Prof J Pérès, of France, was appointed the new president

The week following the Congress was the occasion of a meeting in New York by the American Rocket Society—"Spaceflight Report to the Nation"

There was perhaps a feeling that the International Astronautical Congress was of not quite such a high technical standard as previous ones, as many Americans seemed to consider the American Rocket Society meeting to be the more important of the two—a view not altogether shared by the European delegates

The opening ceremony on Monday was followed by a reception and buffet at the Bolling Air Force Base, where Dr Theodore von Kármán was very much in evidence among the delegates

The technical sessions started at 9 a m on October, 3 with three simultaneous sessions on space propulsion, astrodynamics and guidance, and the Fourth Colloquium on the Law of Outer Space (the Third Colloquium was held in Stockholm in 1960).

The session on space propulsion had two lectures from British delegates, the first by Mr A W T Mottram (Bristol Siddeley Engines, Ltd , Coventry) entitled "Propulsion of the Final Stage of a Satellite Launcher using Liquid Hydrogen as Fuel". Although this was the first lecture of the morning, it was well attended and there was a good discussion, although Americans in the audience were perhaps a little reluctant to describe some of their more recent failures in this field It must be remembered that liquid hydrogen has not yet been used successfully to place a satellite in orbit, and that it was announced during the course of the Congress that the *Centaur* rocket using liquid hydrogen as a fuel has been officially set back eight months

The other British paper, "An Examination of the Characteristics of Propulsion Systems for Inter-Orbital Transfer", by P A. E Stewart (Hawker Siddeley Aviation) was read in his absence by his colleague, Dr. W. F. Hilton. This described the more exotic forms of propulsion, including an omnidirectional method of focusing the Sun's rays for the direct heating of liquid hydrogen for use as a working substance.

Undoubtedly the most noteworthy paper of the morning was by another British delegate, Arthur C Clarke (Clarke-Wilson Associates, Colombo), under the title "The Social Impact of Communications Satellites" This was presented during the Space Law Colloquium and attracted widespread interest A future state of affairs where worldwide communications are as cheap and reliable as our present local communications was investigated. and its effects on social behaviour and trade were discussed Mr Clarke is, of course, well known for having started the idea of communications satellites by his article in October 1945 in *The Wireless World,* and indeed a reprint of this article was issued to all delegates

The Space Law Colloquium continued in the afternoon and there was a session on energy conversion and yet another simultaneous session on astrodynamics and guidance This last subject was treated as a round-table topic where a number of contributors made both prepared and unprepared comments, and included Prof Zdenek Kopal (University of Manchester)

On October 4 the round-table concept was continued with a discussion on exploration of the solar system by radar and radio astronomy, the Moon and Venus being considered in the morning and Jupiter and future experiments in the afternoon The radio reflexion experiments from the surface of the Moon appear to show fairly conclusively that much of the Moon is covered with a layer of dust having a thickness less than 1 cm The session on Jupiter was of interest on account of the detailed description of the radio emissions from the Great Red Spot The nature of these emissions is now fairly well established, but their cause appears to remain a mystery

The most significant communication at the Conference was given by the Russian delegation, who revealed that their cosmonaut Titov was space-sick throughout the duration of his 24-hr trip around the Earth, although this did not prevent him from sleeping in accordance with plans, or from carrying out routine duties which had been assigned to him

On October 5 the weather was fortunately much better, and the now traditional conference boat-trip was made down the River Potomac past the Naval Research Laboratory's radio telescope, on to Mount Vernon This informal occasion probably gives more opportunity for relaxed discussion between *ad hoc* groups of experts than is possible in the more formal atmosphere of the conference hall The Congress banquet was held in the evening and was addressed by Academician Sedov

On October 6 another British paper was presented, "Blue Streak as First Stage of a Satellite Launcher", by G K C Pardoe This described the present position of Britain's only large rocket, based on the design of the American *Atlas* rocket, which is the largest they have attempted to fire to date No particular reference was made to possible British or European payloads, although possible European collaboration in the future was mentioned Simultaneously, there was a round-table meeting on space communications, but most amazingly no reference was made to the use of radio, which is of course the obvious way for exploiting space for communications purposes The signals to be conveyed would be modulated on to beams of light emitted from optical masers This method gives a promise of tremendous band-width at some remote time in the future Use of ultra-violet light for communications was proposed by Mr J W Ogland, and one rather speculative paper suggested the use of γ-rays for communications If the vehicle is propelled by a nuclear rocket, the γ-rays are available as a by-product and some form of hinged lead sheet has to be contrived for signalling purposes This method is limited to use in space in the absence of any atmosphere and was shown to work at ranges up to 100,000 miles but the signalling frequency is limited to one cycle per second

Finally, on October 7, delegates were taken on a tour of the NASA Goddard Space Flight Center at Goddard Maryland

W F HILTON

THE VEHICLE DRIVER

A MEETING of the British Occupational Hygiene Society was held at the Traffic and Safety Division of the Road Research Laboratory during November 9–10 Six papers were read and discussed, for the first two, which dealt with bus drivers the chair was taken by Dr L G Norman, the president of the Society

Examination by Dr P Froggatt of data from Northern Ireland revealed that a curve of accident-rate plotted against age of driver had a broad minimum over the ages 45–55 years which was due to the beneficial results of experience being opposed by the decline in performance with advancing age The accident-rate of experienced drivers rose above 50 years of age

Mr C J Cornwall had examined the records of London bus drivers for the period 1957–59 for which the average rate was 1 37 accidents per driver-year on a mileage of about 14,000 Accidents were associated with traffic density The accident-rate fell with increasing experience more rapidly than it rose with age, the fall was marked up to 47 years and slower up to 70 Replacements of old drivers by younger men would increase the number of accidents

Dr R J Smeed, deputy director of the Road Research Laboratory, occupied the chair during a session which was opened by Mr W Gissane, who described the nature and cause of injuries resulting from motor-car accidents in a city Squadron-Leader D I Fryer told of the development of safety belts in aircraft, going back to Colonel Cody, who was the first man to fly a powered machine in England The design and testing of modern safety-belts were described in detail, and the value of rearwards-facing seats, adequately attached to the airframe, was emphasized

Road experience with safety belts was dealt with by Dr A J Moreland, who approached the problem of assessing accidents quantitatively by defining a damage index This number was evaluated from the damage to chassis, compartment and bodywork When divided by the weight of the motor-car it correlated well with the difference between the squares of the velocities of the objects coming into contact

The damage index divided by weight was used as a basis for comparing the frequency of casualties of various degrees Fatalities commenced at a figure near 15 and rose steadily, serious injuries rose from near the origin while slight injuries attained a maximum at about 25

Safety belts of good design, firmly attached, could prove beneficial, but there were suggestions that people drove faster when wearing them, and they did not check the forward velocity of the head on impact or protect it from objects flung forward from the rear The steering arrangements, likewise, might either promote injury or provide protection

The final paper was delivered by Mr I D Brown with Prof D D Reid in the chair Observations of police and other skilled drivers had been used in an attempt to relate driving performance to fatigue and distraction It seemed likely that there was spare capacity to draw on in case of need and that fatigue from general occupations before driving might be more serious than that induced by driving Tests of distraction by using tape recordings in which the subject was either interested, or not interested, were also carried out

The Road Research Laboratory demonstrated the telemetering of movements of the controls of a vehicle under way, of recording what happens in an accident and of experimental collisions The incorrect basis of early tests on motor-cycle crash-helmets was shown and specimens illustrated the protection afforded by helmets and the distribution of the injuries of motor-cyclists

The bulk of the meeting was concerned with the results of accidents and diminution of their effects on people, little attention was given to the prevention of motor-car accidents by methods within the control of the vehicle driver The papers and discussion will be published in the *Annals of Occupational Hygiene*

C. N DAVIES

MECHANISMS OF VIRUS INFECTIONS

A DISCUSSION meeting of the Royal Society, arranged by Prof Wilson Smith, on the subject of "Mechanisms of Virus Infections", was held on November 2 Owing to the large numbers attending, the meeting was transferred, by courtesy of Sir Lawrence Bragg, to the lecture hall of the Royal Institution The president of the Royal Society, Sir Howard Florey, took the chair

In his introduction, Prof Wilson Smith traced briefly the progress of virological knowledge from the early almost metaphysical questioning into the nature of viruses to the present wealth of information regarding their chemical constitution, structure and intracellular behaviour. He wondered, however, whether these particular aspects were not in danger of being over-emphasized at the expense of more traditional problems relating to virus disease The natural history of any virus disease is intimately related to the survival cycle of the virus concerned and, in the metazoon host, this cycle is necessarily complex The route of infection and primary lodgement, paths and mechanisms of spread through the host, replication and ultimate release must be considered at the various levels of the cell, the intact host and the host population It was with this in mind that the present programme had been built up around the concept of the survival cycle

Prof A W Downie (University of Liverpool) opened the discussion with a paper on "Mechanisms of Virus Entry and Spread within the Host (Animal Viruses)" Although a rapid survey of the various routes of infection known to occur was given to illustrate the extent of the subject, and problems associated with the question of neural spread in such diseases as poliomyelitis, herpes and pseudo-rabies were briefly discussed, the paper was centred on the pathogenesis of disease in the pox group of viruses Fenner's detailed work on ectromelia has laid a pattern which serves as a standard of reference for investigations with other members of this group, and a study of the highly lethal rabbit pox infection shows that it follows the same general course The main difference is that the stages of primary and secondary lodgement with final involvement of the skin, and of primary and secondary viræmia, are less well defined in rabbit pox than in mouse pox Despite thorough investigation of animals infected by the intra-nasal route, no primary lesion is identifiable although virus can be readily demonstrated in the tissues of the nasal passages and trachea The blood contains virus as early as the second day after infection and thereafter remains positive Clinical disease develops on the fourth day The finding that provoked the greatest interest and discussion was that animals do not become infectious by contact until the fifth or sixth day, at least 24 hr after the onset of clinical disease, a finding closely similar to that in human smallpox Following intranasal infection, virus may be isolated from the tissues of the upper respiratory tract in rabbit pox, and smallpox virus is presumed to invade by this route in the majority of human cases Why then is the patient not infective during the incubation period ? Dr C H Cadman (Scottish Horticultural Research Institute) dealt with the same subject in its relation to plant viruses and pointed out that there is an essential difference in the problems involved, since plant viruses are unable to effect entry into the tissues without external aid Trauma is an essential prerequisite to infection and is usually inflicted in Nature by insect vectors In the laboratory the necessary damage is achieved by rubbing the leaf, but the inefficiency of this procedure may be gauged from the fact that about 10^6 infective particles are necessary in order to produce a lesion. Further, since the plant does not possess conveniently isolated internal organs which can be segregated by dissection and to which the virus can track, spread of virus cannot be followed as in the animal host It is probable that virus spreads in the translocation stream, but if so the form of the virus at this time is not known Since certain viruses are apparently capable of dispensing permanently with their protein coat, it is possible that spread within the plant occurs in the form of ribonucleic acid The possible role of plasmodesmata and the problem presented by the fact that virus appears to spread through callus tissue cultures just as fast as through intact plant tissues were also discussed.

It was clear from both these papers, in their different contexts, that there is a long way to go before the problems of virus invasion of host tissues can be considered to be satisfactorily explained

"Intracellular Replication Mechanisms" were discussed by Prof M Stoker (University of Glasgow), who considered the subject from the point of view of the interrelationship of virus growth to cell growth The types of interrelationship exemplified by bacteriophage infection are (1) the extreme virulence found in the *T*-even phage where adsorption of the protein coat is sufficient to cause immediate death of the cell with breakdown of deoxyribonucleic acid; (2) intermediate virulence where the host cell is not immediately killed but cell division is prevented, and (3) the avirulent prophage relationship In the case of animal viruses, infection usually results in death of the cell, and the difficulties in demonstrating non-cytopathic infection of cells were discussed in detail For proof it is necessary to study isolates of single cells and demonstrate, first, release of virus and, second, cell division in that order

Prof Stoker concluded that there is as yet no satisfactory evidence for infections of this type with normally cytopathogenic viruses, but this has recently been acquired by Rubens with the Rous sarcoma virus so that this virus, which is not normally cytopathogenic, is the only one for which the formal criteria have been satisfied In the case of polyoma virus, either cytopathic effect or cell transformation may follow infection *in vitro*, but in the latter case, it has not proved possible to demonstrate virus in the transformed cells and these remain super-infectable with polyoma virus, albeit with difficulty. It must be concluded that persistence of the virus is not necessary for these cells to retain their character once transformation has occurred

Thus three types of non-cytopathogenic relationship appear to be possible In the case of the Rous virus both virus and cell multiply with the intermittent release of infective virus, in lysogenic bacteria both multiply together but virus is not released without induction and death of the cell occurring, and finally with polyoma the virus may induce a cell transformation without itself persisting

Dr A Isaacs (National Institute for Medical Research) considered "Interference Phenomena" as a further aspect of intracellular behaviour Many interference phenomena have now been shown to be mediated by interferon, and the properties of this substance were described It is a protein of molecular weight 63,000 which is produced by all vertebrate tissues so far tested All viruses examined have been found to provoke production of interferon and all are to some extent susceptible to its action In its protective action it possesses some specificity for the species in which it is produced It is non-toxic at viral inhibitory concentrations and does not inhibit cell division In infected cells it suppresses the production of viral nucleic acid, possibly through its inhibitory activity against oxidative processes providing the energy for synthesis As might be expected, therefore, it is found that viruses depending on oxidative processes for their replication are more strongly inhibited than those which do not have this dependence

The possible role of interferon in recovery from virus infections was discussed and some interesting speculations added on the possibility that the action of interferon in virus infections is incidental to its role in the normal cell. Dr Isaacs suggested that its function might in fact be that of excluding extraneous ribonucleic acid of whatever nature It is not formed during the first third of chick embryonic life when ribonucleic acid might be acting as a vital intermediary in the processes of morphogenesis, but thereafter is formed in increasing amounts in response to the appropriate stimulus It might be that its formation in later embryonic life is a mechanism for the protection of the tissues from unwanted morphogenetic stimuli This suggestion aroused some argument and it was pointed out that interferon does not exclude viral ribonucleic acid from the cell but apparently suppresses its formation.

The last paper on cellular relationships of virus was given by Prof G Belyavin (University College Hospital Medical School, London) on "Latency in Virus Infections" Prof Belyavin treated the subject from a purely theoretical point of view and demonstrated by means of a mathematical model that in any system where persistence of infection depends on a balance between the rate of replication of virus and the rate of replication of cells, an impossibly critical state would exist Such a system would inevitably lead either to the virus gaining the upper hand with eventual destruction of the whole cell population, or to cell multiplication outstripping virus multiplication with the elimination of the latter The assumptions on which the model was constructed did not include variation in the susceptibility of the cell population or the role taken by such substances as interferon The intervention of some such factors would be essential if a stable balance between virus and host cells were to be achieved

Epidemiological factors in relation to animal and plant virus diseases respectively were presented by Prof F. J Fenner (Australian National University) and Dr L Broadbent (Glasshouse Crops Research Institute) These two papers provided an interesting comparison of the problems in these two fields, the more so as Prof Fenner confined himself to a discussion of myxomatosis, a vector-transmitted disease A comparison of the Brazilian, Californian and Australian viruses in rabbits native to those regions suggests that, in the establishment of the disease in Nature, natural selection acts not on the virus as such but on the factor of transmissibility Thus the three types of virus are capable of infecting the Californian rabbit *S buchmani*, but whereas the attenuated Australian strain fails to give detectable virus in the skin lesions and the South American strain gives a titre of only 10^4/gm, the Californian virus achieves a titre of 10^8/gm and only the last is found to be transmissible by mosquitoes In Australia since 1952, the original virus, which killed close on 100 per cent of infected animals, has been largely replaced by less virulent variants The fall in mortality has not, however, been extreme or progressive, and the dominant strains have for some years remained in the 'grade III' category in which mortality is about 90 per cent; but since the infected rabbits live longer, the virus is available for transmission for a period of about 15 days as against 5 days with the highly virulent strains However, the increase in the numbers of genetically resistant rabbits may ultimately favour the more virulent virus.

The highly complex interplay of factors governing the epidemiology of myxomatosis was reflected in the field of plant viruses Dr Broadbent dealt with the epidemiology of plant virus diseases in wider terms, but the main interest in his paper lay not in the artificial spread of viruses by human agency or even by contact, but in the intricacies governing its transmission by vectors While the nature and static habits of plants eliminate the complications arising from behaviour patterns, they equally introduce factors specific to plant epidemiology Thus, while it is easy to understand that the size of plants and their position relative to each other and to sources of infection external to the crop must influence spread of infection, the results of the microclimate within the crop are more subtle. If plants are closely spaced, the transfer of vectors will be facilitated, but this may be offset by the development of temperature and humidity conditions within the crop which are not tolerable to them The vector will then be confined to the new shoots which may contain little virus Similarly, plants are in general more susceptible to infection when young, so that climatic influences on the time of greatest prevalence of the vector may determine whether or not infection is widespread irrespective of whether the vector is particularly numerous Despite these factors, which have no real counterpart in the animal virus field, there are more similarities than differences apparent in the epidemiology of plant and animal viruses and Dr Broadbent's paper served to illustrate some of these For example, some viruses, such as potato virus *Y*, can be picked up in a few seconds feeding and immediately spread to uninfected hosts These viruses do not persist in the vector for more than a few hours Others, such as potato leaf roll, require prolonged feeding to infect the vector, cannot be transmitted before the lapse of a latent period, and thereafter persist in the vector for many weeks. This contrast is very similar to that between myxomatosis and yellow fever

Finally, the damage which virus infection inflicts on the host was discussed by Dr J C N Westwood (Microbiological Research Establishment, Porton) in relation to the intact host and by Dr Alison Newton (University of Cambridge) at the cellular level Dr Westwood discussed "Virus Toxicity" and its possible role in the production of disease and ultimately death in fatal virus infections The term 'virus toxicity' was originally coined to cover the production, by massive doses of virus, of lesions or death in susceptible or non-susceptible animals without the occurrence of multiplication of the virus The toxic factor has always been inseparably associated with the virus particle itself Since virus disease is normally initiated by small doses of virus and accompanied by multiplication, it has seemed unlikely that 'toxicity' could be involved, and the latter has always been regarded as a freak laboratory phenomenon unassociated with production of disease It was suggested that this concept might be wrong Experiments were described which showed that the toxicity of rabbit pox virus is associated with a partial cycle of replication, as is the toxicity of other viruses in which such partial cycles have been sought Death in rabbit pox is preceded by the abrupt onset of shock, with some evidence of increased capillary permeability, and the clinical picture can best be explained by the presence of some toxic factor in the blood During the four days preceding death in acutely fatal infections, the virus concentration in the blood may rise to as high as 10^6 infective units/ml and similar concentrations occur in fatal smallpox and herpes infections in man The cytotoxic effect of such virus concentrations on the capillary endothelium could be the cause of the increase in capillary permeability and so precipitate the animal into shock Since no toxic factor other than the virus has ever been demonstrated to result from cell-virus interaction, the possible role of direct virus toxicity in disease must be seriously considered

Damage to the intact host depends on the damage produced at the cellular level, and Dr Newton considered the "Biochemical Aspects of Virus Infectivity" in relation to modification of cellular metabolism The main modifications are found first in the production of new virus and second in changes in the nucleic acid and protein synthesis Viruses which multiply in the cytoplasm make less use of the cell metabolism—for example, vaccinia virus does not affect the metabolism of deoxyribonucleic acid—and such viruses probably produce their damaging effects by competition for metabolites Those which multiply in the nucleus produce a more profound effect, since they must not only compete for metabolites but must also overcome the normal control processes of the cell Thus pre-labelling of the cellular deoxyribonucleic acid with tracer thymidine shows that herpes virus causes a rapid breakdown of cell deoxyribonucleic acid probably due to increased deoxyribonuclease activity similar to the increased ribonuclease activity stimulated by poliovirus It also stimulates synthesis of deoxyribonucleic acid These changes must damage the control mechanisms of the cell, and interfere with synthetic activities in the host In some viruses, such as encephalomyocarditis, viral ribonucleic acid is elaborated in the nucleus and protein in the cytoplasm It is probable that in these instances cytoplasmic protein metabolism is governed by viral ribonucleic acid which migrates from the nucleus The production of cell damage does not depend on completion of the multiplication cycle of the virus, for example, with poliovirus, herpes and rabbit pox viruses, inhibition of infective virus production does not prevent cell destruction It was suggested that cell damage results from the release of lysozomes, disruption of the controlling mechanism of the cell, competition for metabolites and disturbance of metabolic balance

The meeting was successful in provoking lively discussion and considerable disagreement on nearly every point raised by the main speakers Dr Sanders, in summing up, congratulated the participants on avoiding all reference to infective nucleic acids, and he also stressed the gulf which still exists between academic virology and virology as applied to disease

J C. N WESTWOOD

COTTON-GROWING IN NIGERIA

AGRICULTURAL progress relies on the pure sciences, on engineering and on economics These cannot come into play until major practical problems have been resolved into their scientific components Resolution is one of the functions of husbandry investigation Recognition of the nature and importance of this function has come only within the past three decades In this same period the other function of husbandry investigation has also been developed, namely, improvement of accepted practices in raising crops and livestock Cultivations, drainage, sowing, grazing, housing of stock and other day-to-day matters were not looked on, formerly, as problems amenable to study they were matters for the farmer's experience and tradition Modern husbandry investigation seeks to improve all working practices by studying their underlying purposes and interpreting their effects

That physical environment is primarily important for agriculture is now an axiom, though some costly flouting of it is yet fresh in memory It is largely through husbandry investigation that scientific attention has been brought to its present intensity in such matters as rainfall characteristics, solar radiation, air temperature, shade, wind and moisture-holding capacity of soils

Some highly successful husbandry investigations on cotton have recently been reported* from the Ministry of Agriculture Research Station at Samaru, Northern Nigeria

Past work at the Station and in its area of interest had revealed a discouraging situation Local yields were 150–200 lb of seed cotton an acre Late sowing partly accounted for this, but earlier sowing in experimental plots gave only 240 lb Assisted by fertilizers and by early planting the maximum yield was 600 lb. At these yields insecticidal protection did not pay Yield in a bad year was only half of that in a good one and in any small field good and bad patches markedly influenced growth and yield An improved variety of cotton, bred at the Station,

---

* Mobility, 0 09

† Mobility, 0 19

(M_F) A_1, 0 14 ± 0 04, A_2, 0·37, B, 0 57 ± 0 04, C, 0 67 ± 0 04, D, 0 79 ± 0 04; E, 0 88 ± 0 04; and F, 1 (9–10 cm in 16 hr) All components moved towards the negative electrode in the same direction as the endosmotic flow when the mucus was applied near (at 5 cm distance) the Whatman No 3 paper bridge (5 × 6 cm.) immersed in the anode vessel of an Evans Electroselenium apparatus Strips were dried immediately with hot air and fixed in absolute ethanol Components were revealed by dyeing (15 min) with 0 5 per cent bromophenol blue in ethanol saturated with mercuric chloride, then washed with several changes of 2 per cent acetic acid[2] They were estimated with an *EEL* scanner after clearing the strips with liquid paraffin in vacuum (3–4 hr) For completeness the fractions absorbed at the origin O and others only discernible as a streak between A_1 and A_2 were also scanned and expressed as a percentage of the total applied Components B and E had similar mobilities to serum albumin and γ_1-globulin, respectively In samples of chronic bronchitis sputum and mucus only components B, D and E reacted with antisera to human serum proteins The results obtained with various conditions are shown in Table 1 The bronchial mucus samples used were uncontaminated with saliva and obtained at bronchoscopy

Components B, D and E appear in all mucus samples and, except in rare instances, are the three major components Component F also appears to be a common constituent but can fall to very low levels Only in the case of rhinorrhœa was it completely absent Chronic bronchitis mucus samples present the simple patterns B, D and E and a generally high level of F Invasion of the lung by carcinoma produces the additional components A_1 and/or C Of the other cases, that of aspergillosis exhibits component A_2 uniquely and has an A_1 component of abnormally low mobility Both these could be the metabolic products of the invading mould Pulmonary alveolar proteinosis mucus contains an abnormally high content of component D

A similar examination of sputum samples, of which the bronchial mucus would constitute a high proportion, showed the same overall picture The cancer sputum samples (from seven patients) again showed additional components (usually C) not present in chronic bronchitis sputum and F was very low (1–3 per cent) Examination of sputa from one chronic bronchitic was commenced immediately after he had a 14-day course of tetracycline The following day he started a 7-day course of chloromycetin and throughout the period under review was having bronchodilators, breathing exercises and vigorous physiotherapy Following this treatment his general condition improved and his sputum gradually decreased from 2½ oz to ½ oz daily Over a period of three weeks analyses showed a remarkable decrease of component F from 17 2 to 4 3 per cent The neuraminic acid content of the sputum varied slightly over the same period from 1 23 to 1 39 per cent Strips stained with the periodic acid–fuchsin sulphite reagent[4] showed positive reactions only with components B, D and E Another chronic bronchitic with a carcinoma in the left hilar area maintained a high F content (9 5–21 5 per cent) throughout a three-week period of treatment with penicillin and achromycin

An alternative method of analysis of the bronchial mucus samples involved the use of the immunological reaction in agar gel diffusion cells[5] with an antiserum raised against human serum proteins Although no anti-F was present, it sufficed to distinguish the mucus of chronic bronchitis (3 lines) from that of patients suffering from bronchial carcinoma (4 lines), hæmoptysis (8 lines) and aspergillosis (at least 10 lines) Further development of this approach with additional antisera raised against component F and against selected whole mucus samples promises to afford a useful addition to methods of analysing bronchial mucus

orcinol[7-9] or anthrone[10] method used. Detection of free sugar spots on paper chromatograms of acid hydrolysates of the protein (3 *N* hydrochloric acid up to 21 hr , 100° C) has not been achieved, possibly because of the low carbohydrate content, strong protein–carbohydrate bonds and/or sugar destruction The major sugar was, however, identified as galactose by a spectrophotometric method[7] and the nature of the spectrum as well as ratios between extinctions at various wave-lengths[7] suggested the presence of lesser amounts of glucose Similar criteria made probable the essential absence of keto-hexose, mannose and pentose The nature of the spectrum from the carbazole reaction[11] tended to eliminate hexuronic acid as a major constituent, while the presence or absence of hexosamine bound in the preponderant glycoprotein has not been definitely established Both hexuronic acid and hexosamine may be present in the scant orthochromatic material or sections stained with toluidine blue Sialic acid was essentially absent as judged by the observation that the tryptophan–perchloric acid test[12] yielded only a light colour, the intensity of which did not greatly exceed that obtained from an equal amount of beef serum albumin The amino-acids of the protein moiety have been examined by 2-dimensional chromatography of acid hydrolysates (6 *N* hydrochloric acid, 24 hr , 100° C) of the lipid-free material followed by ninhydrin development and visual comparison with spots given by an equal amount of bovine serum albumin of known amino-acid composition[13] which was hydrolysed in a manner identical with that used for the unknown protein Several comparisons were made for each amino-acid and the average results were accepted as a reasonable basis for calculating approximate amino-acid composition It was assumed that, for most amino-acids, errors associated with destruction or other variables were approximately the same for both preparations Perhaps of most immediate interest here is the fact that the protein is characterized by unusually large amounts of serine This substance was estimated to comprise approximately 15 per cent of the total amino-acid residue content on a weight basis The glutamic acid content was also found high as compared with many proteins (about 20 per cent) and aspartic acid low (about 5 per cent) Cystine was quite low, but quantitative estimates are not justified because of large variability in the destruction of this amino-acid as a function of the carbohydrate content of the hydrolysis medium[14] The levels of amino-acids did not vary significantly between batches obtained from normal and dystrophic animals It is not certain whether there are other quantitative differences in the composition of the two types of calculi

The mouse calculus material exhibits a chemical make-up which is markedly different from the organic matrix of crystallized human[15,16] or bovine[17] calculi and from a large number of mammalian proteins for which recorded data have been examined The composition is similar in a general way to that of the Bence Jones protein with regard to the contents of phospholipid, cholesterol and carbohydrate[18] as well as the high serine-level[19] but deviates radically in the contents of other amino-acids The significance of the influence of sex and of muscular dystrophy on the incidence of calculus excretion remains to be determined, however, beyond these considerations, it seems possible that the strain 129 mice may be a useful source of experimental animals for the study of calculus formation

MUCOPROTEINS OF BRONCHIAL MUCUS

By Dr M. Z ATASSI and Dr S A BARKER
Chemistry Department, University of Birmingham

Dr L E. HOUGHTON
Harefield Hospital

AND

K S MULLARD
Southampton Chest Hospital

WARFVINGE[1] found that analyses of tracheo-bronchial secretions by electrophoresis on Whatman No 1 paper in barbiturate buffer *p*H 8 6, revealed at the most three mobile mucoproteins, the bulk of the material being absorbed at the origin

We have found that electrophoretic separation (16 hr) on cellulose acetate foil (5 × 25 cm) in citrate buffer (*p*H 5 1, μ 0 05) at 175–180 V and 0 6 m amp /cm revealed as many as seven well-defined components having electrophoretic mobilities

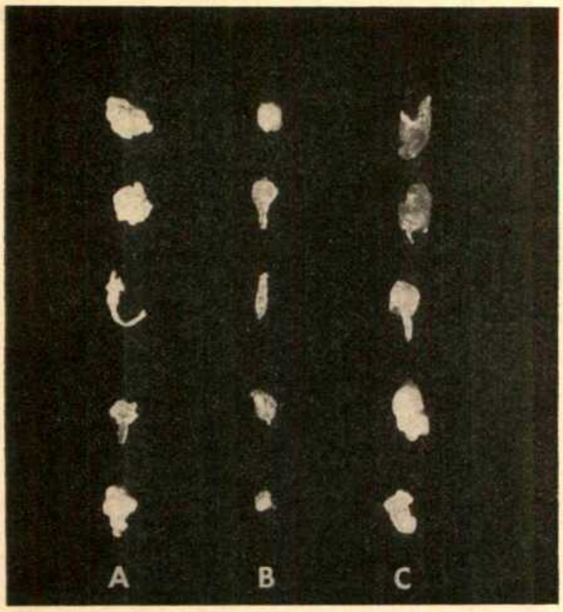

Fig. 1. Urinary calculi excreted by strain 129 mice. *A*, from homozygous normal mice; *B*, from 3–5 month-old male dystrophic mice; *C*, from male dystrophic mice in a more advanced stage of the disease. (× *c*. 2)

and staining techniques. Photomicrographs of portions of sections stained with various reagents are shown in Fig. 2. An outer wall was usually apparent and was defined best with hæmatoxylin and eosin stains (Fig. 2*A*). The portion of the wall shown is much wider than was generally seen but serves to illustrate certain small areas which stain blue with hæmatoxylin and appear dark in Fig. 2*A*. Since these areas did not react positively to Feulgen stain, they may represent minute zones of calcification rather than deoxyribonucleoprotein. The remainder and by far the major portion of the concretion showed only the light pink colour of the non-specific eosin. A strongly positive periodic acid–Schiff reaction (Fig. 2*B*) was shown throughout the calculi, indicating the presence of significant amounts of carbohydrate. Toluidine blue stain (Fig. 2*C*) showed thin sparse concentric rings of orthochromatic material only near the periphery while the remainder of the section reacted negatively to this stain suggesting that acid mucopolysaccharides are not essential for the formation of the calculi. Von Kossa stain for insoluble phosphates, carbonates and soaps gave a negative reaction and a sparse positive response was obtained to sudan IV at room temperature, suggesting small amounts of low-melting lipid. No evidence of a nidus with a separate identity was seen.

Water-insoluble protein comprised about 75 per cent of the original wet weight of the calculi and water-soluble solids about 8 per cent. To prepare the protein for chemical analysis, the calculi were ground in a mortar with distilled water and the insoluble residue was centrifuged, washed twice and dried to constant weight. Despite the fact that the availability of material has been quite limited, the use of sensitive micro-techniques has permitted qualitative identifications and quantitative estimates of its major constituents, and some of the more important results are reported briefly here. The complex protein exhibited an unexpectedly high nitrogen content (16·9 per cent in one batch assayed by digestion and Nesslerization[2]) and contained 1·5–2 per cent easily extractable lipid (four extractions of 30–45 min. each with 3 : 1 ethanol–ether at about 75° C.). About 20 per cent of the lipid was phospholipid as determined by conversion of inorganic phosphorus levels (methods of Fiske and Subbarow[3]) in lipid digests to 'average' phospholipid values according to Gortner[4]. Cholesterol, assayed by the method of Searcy and Bergquist[5], comprised approximately 10 per cent of the lipid. Both free and esterified forms were present but in varying ratio. Amide nitrogen, analysed in *N* hydrochloric acid hydrolysates (4 hr., 100° C.) by the Conway diffusion method[6], constituted about 1·3 per cent of the lipid-free protein. Carbohydrate was present to the extent of a few per cent although the values have varied with the

by Medawar[18]). This theory postulates that all immunologically immature cells are susceptible to induction of tolerance, regardless of whether they are in the embryo or adult. The exposure of adult animals to antigenic stimuli should therefore set in motion two processes: sensitization of mature cells and induction of tolerance in immature cells. Tolerance would normally be masked by the immune response, but if the sensitized cells were to be removed by some means (as for example by prolonged contact with the antigens) the lymphoid cell population of adult animals might be changed progressively from a predominantly sensitized to a predominantly tolerant one[19]. Although nothing is at present known of the specificity or the mechanism of the striking effect described by Shapiro *et al.*[17] (for example, is it due to central or efferent inhibition?) their experiments are open to this interpretation. That smaller genetic differences can be overcome by a much less-formidable antigen dose suggests the possibility that the number of sensitized cells involved in such a situation is considerably smaller.

Our own results also could be accommodated by the stem-cell theory, the neonatal or very young mouse being vastly more amenable to induction of tolerance across the *H*-2 barrier than the 'adolescent' or adult mouse precisely because its population of lymphoid cells is still predominantly immature. The occurrence of increasing numbers of immunologically mature cells in developing animals would therefore be sufficient to account for the age-dependence of induction of tolerance. The experimental evidence of Howard and Michie[9] certainly suggests that even the neonatal mouse may already have some immunologically mature cells.

This alternative interpretation, according to which the difference between unresponsiveness in adults and tolerance in neonatal animals would be one of strategy rather than of basic mechanism, is of course highly speculative. Simonsen's[20] observation that adult lymphoid cell populations may, in time, develop tolerance of the host's tissue antigens while retaining the ability to respond to the tissue antigens of other mouse strains suggests that it may not be well founded; but much depends on the elucidation of the mechanism which underlies this observation.

We wish to thank Prof. P. B. Medawar for his interest in this work and for his much-valued criticisms.

EXCRETION OF UNCRYSTALLIZED URINARY CALCULI COMPOSED OF GLYCOLIPO-PROTEIN BY NORMAL AND MUSCULAR DYSTROPHIC MICE

By C. McGAUGHEY

Medical Research Programs, Veterans Administration Hospital, Long Beach, California

STRAIN 129 mice, susceptible to a hereditary myopathy[1], excrete urinary calculi examples of which are reproduced in Fig. 1. These bodies have been located *in situ*, floating freely in the urinary bladder, and are probably vesical calculi. They may appear either hyaline or opaque and sometimes exhibit bizarre forms. The largest calculi, the maximum length of which was 3·5 mm. (Fig. 1*C*), were obtained from two dystrophic male mice which were in a more advanced stage of the disease than any of the other animals tested, with the hind legs extended and non-functional. Calculus excretion by one dystrophic and one heterozygous normal animal began at about three months of age.

The rate at which the calculi are excreted is a function of sex and of the presence or absence of muscular dystrophy (Table 1). The results shown are for representative animals; however, all dystrophic males studied excreted calculi at a greater rate than any of the normal males, and normal females have never yet been observed to pass a calculus. Dystrophic females occasionally yielded tiny amorphous hyaline bodies.

Sections were prepared for histochemical examination by formalin fixation of the concretions followed by conventional paraffin block mounting, slicing

Table 1. RATES OF EXCRETION OF URINARY CALCULI BY STRAIN 129 MICE

Type of mouse	Sex	Age* (months)	Collection period (days)	Rate (calculi/ 10 days)
Normal (Homozygous)	M	5	61	1
Normal (Homozygous)	M	3	36	0
Normal (Homozygous)	F	3	36	0
Normal (Heterozygous)	M	5	36	4
Normal (Heterozygous)	F	5	29	0
Dystrophic	M	3	63	6
Dystrophic	M	—	61	13
Dystrophic	M	—	18	8
Dystrophic	F	5	36	0

* Age at which collection was begun.

—, age unknown but the mouse was in an advanced stage of dystrophy and died during the collection period.

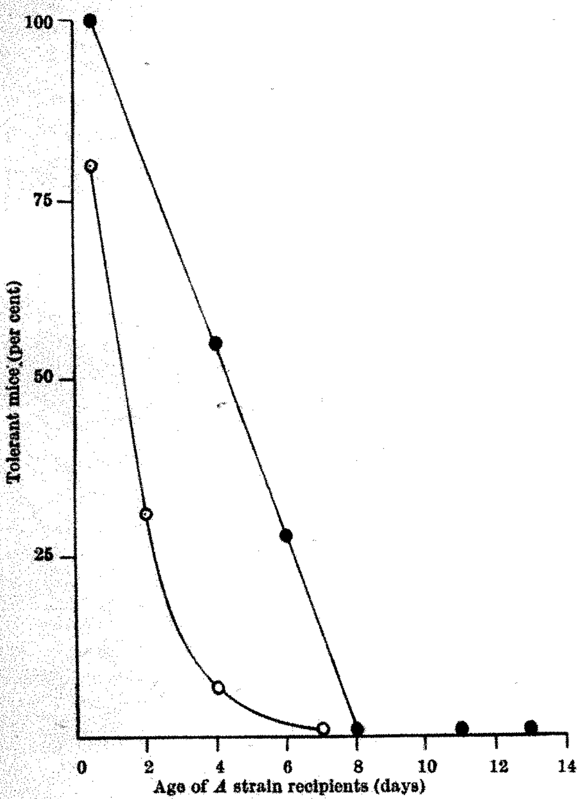

Fig. 2. Age-dependence of tolerance induction in *A* strain mice. Criterion of tolerance: skin graft survival at 5 × control median survival time (= 63 days). ○——○, 4–10 × 10^6 parental strain (*CBA*) cells per mouse. ●——●, 5 × 10^6 F_1 hybrid cells (*CBA/A*) per gm. body-weight

of these mice gave a weak second-set response, that is, they behaved as if the allogeneic (= homologous in the old terminology; see Gorer, Loutit, and Micklem[3]) cells had sensitized them.

The 11- and 12-day-old mice in the experiments described so far were injected with doses of cells which, scaled down according to body-weight, would have been more than adequate to bring about tolerance in neonatal mice. In order to investigate still further the relationship between tolerance and immunological paralysis groups of 12-day-old mice were injected with up to 10 times the weight-adjusted dose of *CBA/A* hybrid spleen cells (max. 3 × 10^8). The results are summarized in Table 1. Of the 26 mice not one was made tolerant by these massive stimuli and the mean survival-time of the grafts actually declined slightly with increasing dose, suggesting that larger numbers of cells sensitized more efficiently. (As the sensitivity elicited by allogeneic lymphoid cells declines relatively rapidly[4,5] a greater expression of sensitivity than that encountered by us could scarcely have been expected.) Hence, confrontation of these mice with a single cellular stimulus, however large, did not lead to the induction of tolerance.

Table 1

Exp. No.	Cell dose	No. of mice	No. of surviving grafts			Approx. MST (days)
			8 days	10 days	12 days	
6	WAD*	19	18	8	5	9½
8	3 × WAD	12	6	1	0	8
10	6 × WAD	2	2	0	–	8
15	6 × WAD	7	3	0	–	
17	4 × WAD i/v 6 × WAD i/p†	5	2	1	1‡	

* WAD, weight-adjusted dose = 5 × 10^6 cells per gm. body-weight = approx. 30 × 10^6 cells per mouse.

† I/p injection carried out on the following day.

‡ Graft destroyed by the thirteenth day.

It may be argued that the shift of the proportion of mice made tolerant in the first post-natal week is due to the fact that in Billingham and Brent's experiments parental strain cells rather than hybrid cells were used and that, in their experiments, the number of tolerant mice was therefore reduced by deaths from runt disease. Such an explanation is unconvincing, for a repetition of their experiments, using a constant number of *CBA/A* hybrid cells instead of *CBA* cells, is giving almost identical results. (This experiment is still in progress.) It is much more likely to represent a true shift produced by the higher antigen dose, an explanation which obliges us to revise our concept of the "neutral" period[6]. Such a period would appear to exist, if at all, only in a relative sense; it evidently depends not only on the degree of genetic affinity between cell donor and recipient[7,8] but also on the number of cells injected. In other words, immunological 'neutrality' for one antigen dose does not necessarily apply to another which is either larger or smaller—a conclusion which is in harmony with the observation that even new-born mice may be capable of immunological responses provided that they are stimulated by rather small doses of allogeneic cells[9]. That tolerance induction during the 'neutral' period should depend on antigen dose is perhaps not too surprising in view of the fact that induction of tolerance in new-born mice is also dependent on dose[1,9,10].

The point which stands out clearly from our results is that induction of tolerance in very young mice is not simply a scaled-down version of the kind of immunological unresponsiveness which can be brought about with soluble proteins in adult animals (for comprehensive reviews, see Chase and Smith[11,12]). Experiments somewhat similar in design but concerned with the induction of tolerance of bovine serum albumin in rabbits have been described by Smith[13], who found that with weight-adjusted doses tolerance could be elicited at birth or 7 and 14 days later, but not when injection was delayed until 21, 28 or 40 days after birth. (See also the work of Dresser[14] with mice.) Smith concluded that "... the induction of tolerance during the neonatal period depends upon special conditions which are unique to this period of life ...". Our own results are not at all at variance with this conclusion.

Nevertheless, it is possible to interpret our results by stipulating that the difference between the neonatal or very young mouse and the adult mouse is quantitative rather than qualitative. Such an alternative interpretation is prompted by findings reported from several other laboratories. (1) Tolerance of male isogenic grafts can be brought about in adult females by a single intravenous inoculation of approx. 20 × 10^6 male spleen cells[15]. (2) If donor and recipient differ only at the *H*–3 histocompatibility locus, adult mice can be sensitized or rendered unresponsive to skin grafts depending on the number of lymphoid cells injected[16] (1–5 × 10^6 cells sensitized, whereas 2 × 10^8 produced unresponsiveness). (3) Adult mice can be made unresponsive, even when donor and recipient strains differ at the *H*–2 locus, if they are injected intravenously and over a prolonged period of time with large numbers of spleen cells[17] (1·5 × 10^9 in 7 weeks).

These observations could be accounted for by the stem-cell theory of tolerance induction (see discussion taneously prevented (effect mentioned in 3), and the net result of efferent bundle activation is to gate out auditory input to the brain.

CELLULAR DOSE AND AGE OF HOST IN THE INDUCTION OF TOLERANCE

By Dr. L. BRENT and Dr. G. GOWLAND

Department of Zoology, University College, London

THERE has so far been no systematic study of the relationship between antigen dose and age of host in the induction of tolerance of tissue homografts. In previous experiments[1] conducted with mouse strains differing at the *H*-2 histo-incompatibility locus a constant number of adult spleen cells (4–10 × 10^6) were injected into groups of mice of various ages and the decline of tolerance induction with increasing age was studied. This decline occurred in the first few days of life and was found to be very rapid: only 13 per cent of *A* strain mice injected on the 4th postnatal day with *CBA* spleen cells showed any significant degree of tolerance when skin-grafted 6 weeks later. This kind of approach is open to the objection[2] that the antigen dose does not keep pace with the increase in weight of the young recipients; our latest experiments, of which a preliminary account is given here, were designed to re-investigate the age-dependence of induction of tolerance with this objection in mind.

The mouse strains were identical with those previously used except that *CBA*/*A* hybrid cell donors were preferred to *CBA* donors in order to avoid the complications of graft-against-host reactions[1]. Spleen cells from hybrid donors were injected into 6 groups of *A* strain mice ranging in age from about 12 hr. to 13 days after birth. Each group comprised 16–20 individuals, and all injections were made intravenously. In the youngest groups the sigmoid sinus or the orbital branch of the anterior facial vein were used[1]; in the older groups, one of the lateral tail veins. The dose of cells was 5 × 10^6/gm. of body-weight (weight-adjusted dose) and the cell suspensions were prepared according to the method described previously.

All mice were grafted with female *CBA*/*A* hybrid skin 55 days after injection. The grafts were inspected 8 days later, that is, at a time when a first-set response can still be clearly distinguished from a second-set response, and they were observed for 100 days. The median survival time of control grafts (*CBA*/*A* hybrid skin on normal adult *A* strain mice) being 12½ days, the grafts were classified according to whether they survived for at least twice the mean survival time (25 days; Fig. 1) or 5 times the mean survival time (63 days; Fig. 2).

The results are set out in Figs. 1 and 2 alongside the original (*constant dose*) data of Billingham and Brent. They show very clearly that, in the first week after birth, the injection of a weight-adjusted dose gave rise to a consistently higher proportion of tolerant animals. For example, in the 4-day-old group the proportion of tolerant mice rose from 13 to 85 per cent, and even in the 6-day-old group it remained at a relatively high level (45 per cent compared with 0 per cent) (Fig. 1). Similar increases become evident when the data are plotted according to our more stringent criterion of tolerance (Fig. 2). Without doubt the use of a weight-adjusted dose added about 4 days to the period in which tolerance could be induced in this particular strain combination.

The second point emerging from these results is that the injection of a standard dose into 12- or 13-day-old mice did not lead to induction of tolerance in a single mouse; on the contrary, a small proportion

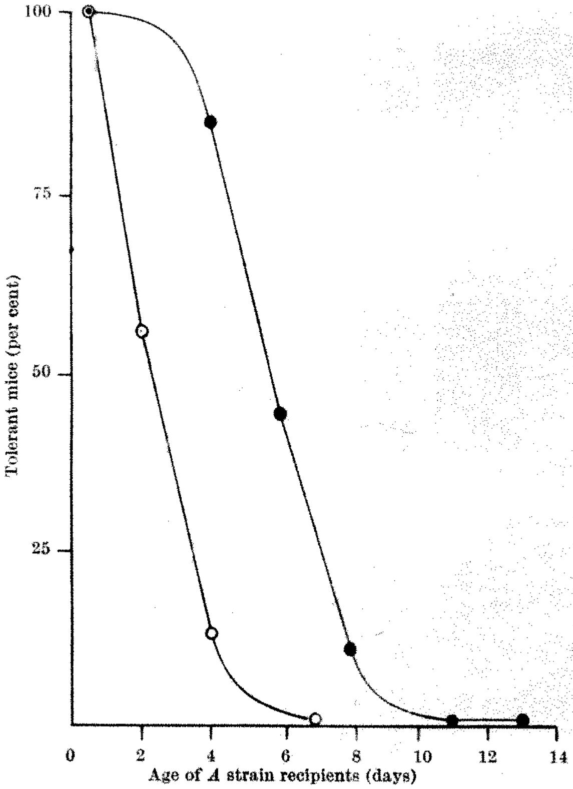

Fig. 1. Age-dependence of tolerance induction in *A* strain mice. Criterion of tolerance: skin graft survival at 2 × control median survival time (= 25 days). ○——○, 4–10 × 10^6 parental strain (*CBA*) cells per mouse. ●——●, 5 × 10^6 F_1 hybrid cells (*CBA*/*A*) per gm. body-weight

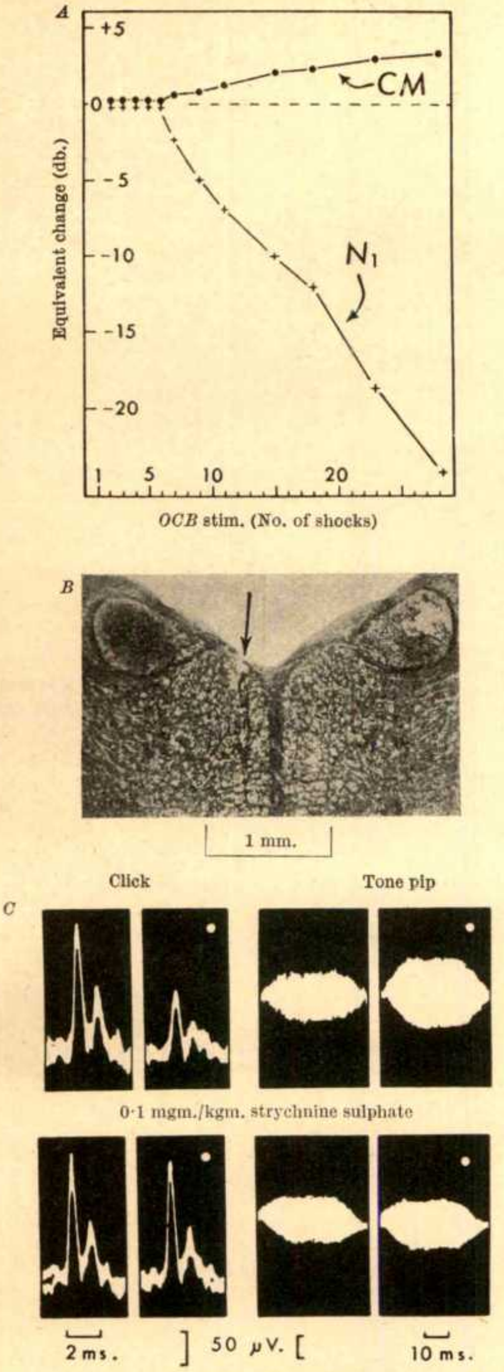

Fig. 1. Cat No. *A*295. Middle ear muscles cut. Clicks or 3 kc./s. tone pips, 30 db. above acoustic threshold, were delivered to the ear 10 msec. after delivery of a train of electric pulses at 300/sec. to the crossed olivo-cochlear bundle (*OCB*). *A*, amplitude changes in cochlear microphonic (*CM*) and neural (N_1) responses to sound as a function of the number of shocks in the preceding train delivered to *OCB*. *B*, histological control: section (modified Bielchowsky) with prussian blue mark of tip of stimulating electrode in *OCB*, between the two facial genua. *C*, oscillograms (several sweeps superimposed) showing suppression of N_1 spike and potentiation of *CM*, before and after strychnine. In the frames marked with a white dot, the sound was preceded by *OCB* stimulation

(*c*) *Neuropharmacology*. The intravenous injection of 0·05–0·15 mgm./kgm. strychnine sulphate which abolishes the N_1 inhibition[5] also eliminates the *CM* potentiation (Fig. 1*C*). The related alkaloid brucine produces the same antagonism to efferent bundle effects. No changes have been observed with metrazol, picrotoxin, ammonium chloride, eserine or dihydro-β-erythroidine.

For quantitative assessment, the changes in response voltage induced by bundle stimulation have been evaluated in relation to the intensity function of responses to sound alone. In many experiments the maximal suppression of N_1 was strikingly powerful, being equivalent to a 24-decibels attenuation of the sound energy. By contrast the maximal *CM* potentiation only amounted to a 3 db. increase (Fig. 1*A*). The two effects are thus of a quite different size, but both have to be considered when discussing the mode of action of the efferent axons on the inner ear and the following implications seem warranted.

(1) Since *CM* is generated in the hair cells of the organ of Corti[6,7] and is a 'receptor' potential[7], the recorded *CM* potentiation implies that the efferent axons must go as far peripherally as the hair-cell membrane. This is a useful cue for electron microscope studies.

(2) In view of the similar neuropharmacological properties, the efferent axons should manufacture and release the same inhibitory chemical transmitter as the axons responsible for post-synaptic inhibition in the cat's spinal cord[8]. Both inhibition of N_1 and potentiation of *CM* are ascribable to this transmitter (Fig. 1*C*).

(3) The olivo-cochlear suppression of N_1 being an obvious case of post-synaptic inhibition would depend on stabilization and possibly hyperpolarization of the terminal membrane of the afferent auditory axon since the latter represents the post-synaptic component in the excitatory afferent synapse between hair cell and auditory axon (Fig. 2).

(4) In order to account for the *CM* potentiation, we further suggest that part of the inhibitory transmitter is released on to the (pre-synaptic) membrane of the hair cell the resting potential of which would be increased by the usual selective change in ionic permeability. The *CM* receptor potential would thereby be potentiated since it is generated as a modulation of the hair cell resting potential (plus endolymphatic potential) by the acoustic transducer effect[6,7]. This would be the first evidence for a lack of restriction of transmitter effect to the post-synaptic membrane. Such a phenomenon might only occur in special and/or primitive synaptic organizations.

(5) The potentiation of the receptor potential is a paradoxical effect since the activation of the auditory axon by sound via the hair cell transducer is simul-

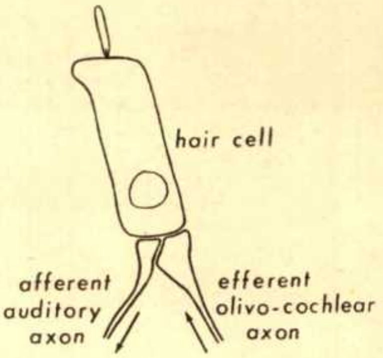

Fig. 2. Tentative diagram of synaptic organization in the organ of Corti, as suggested by the physiological evidence discussed. Electron microscope data would appear compatible with the occurrence of two types of axon terminals at the base of the hair cell, but the efferent endings have not yet been precisely identified

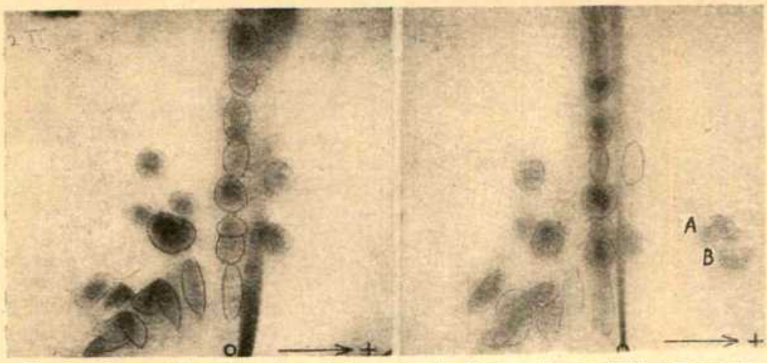

Fig. 3. Fingerprints of trypsin and chymotrypsin digests of hæmoglobin components separated on carboxymethyl cellulose columns described in Fig. 1. Paper electrophoresis of fraction II (left) and III (right) of the 'experimental' components applied at the origin (*O*) was carried out in the horizontal direction (cathode on the left), in pyridine/glacial acetic acid/water (10 : 0·4 : 90), *p*H 6·4 buffer, followed by paper chromatography in the vertical direction (ascending) using butanol/acetic acid/water (3 : 1 : 1) as solvent. Two peptides are demonstrable in the abnormal hæmoglobin component (*A* and *B*). No similar peptides were present in the other fractions

produced by nucleoproteins entering the cell and successfully competing or interfering with normal information transfer within the cell. (In unpublished experiments carried out in this laboratory, using similar culture conditions described here, influx of phosphorus-32-labelled DNA into rabbit marrow cells has been demonstrated[12].) It is unlikely that the abnormal hæmoglobins are due to artefacts such as denaturation or altered pigment formation since a distinctive peptide pattern has been observed in two experiments where fingerprint characteristics have been investigated. Experiments investigating the exact nature of the agent producing the change as well as structural considerations of the abnormal hæmoglobin are in progress.

In summary, abnormal hæmoglobin formation can be induced in human megaloblastic marrow cells exposed to nucleoproteins derived from sickle-cell anæmia. The data are not sufficient to identify with certainty either the product formed or the agent producing these changes. The electrophoretic behaviour of the abnormal hæmoglobin and its elution from carboxymethyl cellulose closely resembles sickle hæmoglobin, but the peptide analysis is distinctly different.

This investigation was supported by a research grant (*C*–4944) from the National Cancer Institute, National Institutes of Health, United States Public Health Service. Portions of this article were presented at the seventy-fourth annual meeting of the Association of American Physicians, May 3, 1961, and are published in the *Transactions* of the Association. We thank Drs. John Spizizen, Jack Pensky and Melvin Schoenberg for valuable advice and support.

MODE OF ACTION OF THE EFFERENT OLIVO-COCHLEAR BUNDLE ON THE INNER EAR

By DR. J. E. DESMEDT and DR. P. MONACO

Laboratoire de Pathologie générale, University of Brussels, Belgium

THE Rasmussen olivo-cochlear bundle[1] represents the most peripheral part of a polysynaptic centrifugal system presumably responsible for control of acoustic input[1,2]. It originates in cells of the superior olive complex and terminates close to the organ of Corti in the inner ear[1]. Direct faradization of the bundle is known to depress acoustic evoked responses[3] and the results to be presented are concerned with the peripheral mechanism of this gating effect.

In experiments on cats (pentobarbitone, chloralose or high spinal section; middle ear muscles stapedius and tensor tympani cauterized; 'Flaxedil' infusion) the auditory nerve compound action potential (N_1) evoked by clicks and the cochlear microphonic potential (*CM*) evoked by tone pips have been recorded through an electrode placed on the round window. Trains of electrical pulses were applied to the crossed olivo-cochlear bundle through bipolar stereotaxic electrodes (Fig. 1*B*) at known intervals before delivery of the testing sound (click or tone pip) to the ear. As illustrated in the upper row of records of Fig. 1*C*, effective stimulation of the efferent bundle produces two effects, namely, inhibition of the N_1 spike[3] and potentiation of *CM* (ref. 4). Our observations suggest that both effects are genuine and that they are simultaneously produced by a chemical transmitter released from the olivo-cochlear axon terminals.

(*a*) *Parameters*. The two effects disclose proportional quantitative changes when the parameters of the preceding bundle stimulation are systematically modified. In the graph of Fig. 1*A*, trains of 1–28 pulses at 300/sec. were delivered to the bundle 10 msec. before the testing sound: changes in N_1 and *CM* appear after the train of 6 shocks and increase in parallel with the number of shocks.

(*b*) *Dissipation*. When the testing sounds are applied at increasing intervals after a standard train, of say, 20 pulses at 400/sec., N_1 suppression and *CM* potentiation appear maximal at the end of the bundle stimulation and dissipate exponentially with a time constant of about 0·15 sec.

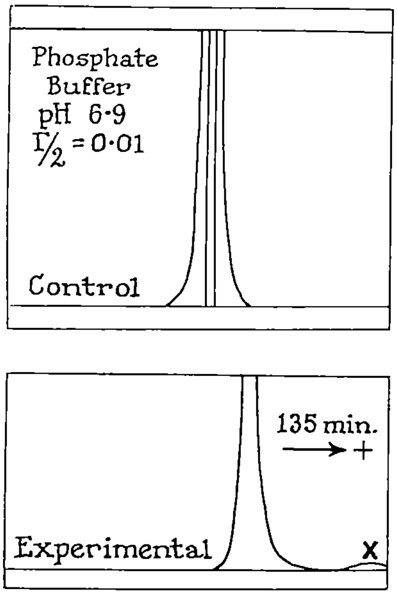

Fig. 1. Tiselius electrophoretic pattern of hæmoglobin derived from megaloblastic marrow incubated with and without sickle cell nucleoproteins. A single peak was observed in the control whereas an additional component (*x*) appeared in the experimental hæmoglobins. (Phosphate buffer, *p*H 6·9, ionic strength 0·1)

To the experimental flask was added 2 mgm. of sickle-cell nucleoproteins dissolved in 2 ml. of 0·9 per cent sodium chloride. The control incubation mixture was identical except that an equivalent volume of saline was substituted for the nucleoproteins. Incubation was carried out for 24 hr. at 37° C. with gentle agitation and the reaction terminated by the addition of deoxyribonuclease and 0·01 *M* magnesium sulphate. The cells were sedimented by centrifugation at low speed and washed 4–6 times, sedimenting each time from about 4 volumes of 0·9 per cent sodium chloride. The cells were lysed by freezing and thawing and the cell ghosts were removed by centrifugation at 30,000*g* for 30 min. The resultant hæmoglobin solutions were dialysed for 3 days against 0·001 *M* phosphate buffer, *p*H 7·2, with three changes of buffer followed by high-speed centrifugation. Altered hæmoglobin formation was detected by various electrophoretic procedures, ion-exchange chromatography and peptide analysis. An unexpected and consistent finding was that the radioactivity present in the hæmoglobin derived from marrow incubated with the nucleoproteins was 2–4 times that present in the control samples. Thus, in the experiment reported in this article, 0·8 per cent of the iron-59 added was incorporated in the control as compared with 2·35 per cent incorporated in the experimental.

The electrophoretic mobility of the hæmoglobins was first compared on either agar-gel or starch-gel and by moving boundary electrophoresis. Abnormal components were demonstrable in the experimental hæmoglobin solutions as compared with the control samples in five of nine experiments. One such component demonstrable by Tiselius electrophoresis is indicated in Fig. 1. Elution of an abnormal component from a carboxymethyl cellulose column[10] was achieved by establishing a *p*H gradient with 0·01 *M* phosphate buffer. This abnormal hæmoglobin component (III, Fig. 2) closely resembled sickle-cell hæmoglobin in its elution behaviour. No difference has been observed between control and experimental carboxymethyl cellulose elution patterns of hæmoglobin when megaloblastic marrow was incubated with DNA derived from normal marrow.

The abnormal component was concentrated by evaporation of the eluates, dialysed in the same manner as described, and a peptide analysis performed. Since there was no comparable peak in the control, the peptide composition of the abnormal component (III, Fig. 2) was compared with the peptide composition of hæmoglobins derived from peaks I and II in both the control and experimental samples. Peptide fingerprints of the hæmoglobins were carried out by the procedure of Ingram[4] using the modified digestion method of Anfinsen *et al.*[11]. Samples were run in pairs under identical conditions using the same quantity of hæmoglobin. Two peptides which are not demonstrable in any other fraction were present in the fingerprint of the abnormal hæmoglobin (*A* and *B*, Fig. 3). This peptide fingerprint does not, however, resemble that derived from sickle-cell hæmoglobin where the abnormal peptide is found in juxtaposition to peptide No. 4. Neither does it resemble the peptide pattern of fœtal hæmoglobin when compared with fingerprints of cord blood obtained by the same technique. An identical abnormal peptide pattern was obtained in another experiment of this type using similar conditions.

The possibility therefore exists that the megaloblasts can be induced to form a new hæmoglobin as the result of altered peptide synthesis and that therefore a phenotypic alteration or mutant has been produced. The electrophoretic behaviour of the abnormal component and its elution from carboxymethyl cellulose columns closely resemble those of sickle-cell hæmoglobin but the peptide analysis is distinctly different. It may be postulated that such a mutant could be

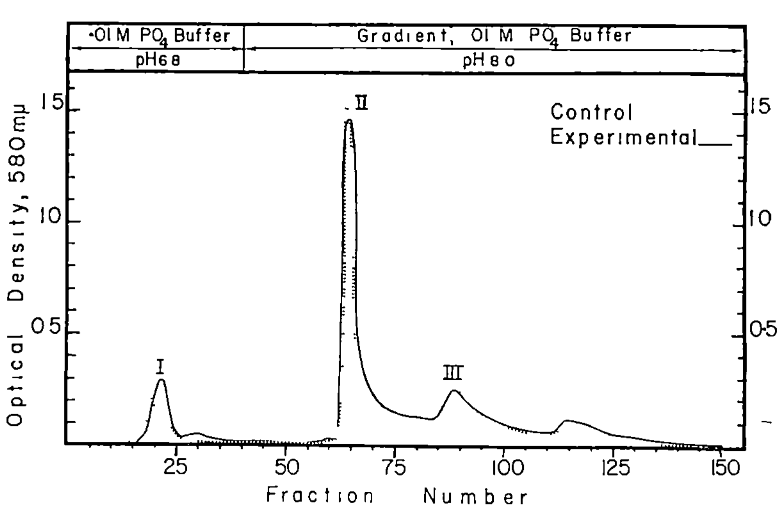

Fig. 2. Separation of hæmoglobin components of megaloblastic marrow incubated with and without sickle-cell nucleoproteins. Approximately 150 mgm. hæmoglobin described in Fig. 1 were introduced on to a carboxymethyl cellulose column (52 × 1·3 cm.) and the hæmoglobins separated by elution with 0·01 *M* phosphate buffer (*p*H 6·8–8·0). 4·0-ml. aliquots were collected at flow-rates of 20 ml. per hour. Hæmoglobin concentration was measured at 580 mμ. An abnormal component (III) was demonstrable in the 'experimental' as compared with the control

organs *in vitro*[3] but to be largely confined to glomerular basement membranes *in vivo*[10].

Since anti-rat and anti-dog placenta sera have been shown to be nephrotoxic, and nephrotoxic sera are always localized on the glomerular basement membranes *in vivo* and *in vitro*, it would appear reasonable to speculate that anti-human placenta sera which are localized on human glomerular basement membrane *in vitro* might also contain glomerular-damaging antibodies among the localizing antibodies. Certainly absence of localization on the human glomerular basement membrane by anti-human placenta sera would be substantial evidence against glomerular-damaging antibodies being present.

Recently, Dixon[11] has shown that repeated intravenous injections of foreign protein produces glomerular damage in rabbits by means of antigen–antibody complexes. These complexes become localized in and damage glomeruli without any immunological specificity for kidney antigen. This alternative method of damaging glomeruli would have to be considered in the etiology of toxæmias of pregnancy because placental antigens might continually leak into the maternal circulation and form antigen–antibody complexes which become localized in glomeruli for non-immunological reasons and damage them.

Although the basement membranes in many organs may contain antigens in common with the maternal human glomerular basement membrane, the placenta is unique during pregnancy. The placenta is the only organ in the body which has the capacity to vary its antigenic structures by paternal contribution to its composition. This variation may be sufficient to cause some of the antigens to appear 'foreign' to the mother yet sufficiently related to cause the antibodies produced to cross-react with closely related antigens in the human glomerular basement membrane and produce glomerular damage. Since the human placenta may be considered a highly vascular structure, rich in antigens closely related to human glomerular basement membrane, it is possible that such antigens, slightly altered, could enter the maternal body and act as an antigenic stimulus. In such cases the maternal human glomerular basement membrane might act as one of the most important and vulnerable target organs.

These preliminary experiments will be reported in greater detail elsewhere[12].

ABNORMAL GLOBIN FORMATION IN HUMAN MEGALOBLASTS

By Prof. AUSTIN S. WEISBERGER and ERNEST P. NOBLE

Department of Medicine and Department of Biochemistry, School of Medicine,
Western Reserve University, Cleveland, Ohio

THE following work was undertaken to determine whether altered production of globin could be induced in human megaloblasts by exposing them *in vitro* to nucleoproteins derived from sickle-cell anæmia. More than thirty biochemically distinct characteristics have been successfully introduced into bacteria by exposing them to deoxyribonucleic acid (DNA) derived from homologous species[1]. Similar work on mammalian cells has been hampered by the obvious difficulties of using such cells as compared with bacteria and also by the difficulty of demonstrating that a successful transfer of genetic information has occurred. The abnormal hæmoglobins, however, provide an approach to such investigations. They are, at present, the only well-investigated system in human biochemical genetics where it can be shown that mutations produce demonstrable alteration in a protein molecule. Thus, Ingram has shown that sickle-cell hæmoglobin differs from normal hæmoglobin by the substitution of valine for glutamic acid in a specific peptide of the β-polypeptide chain[2–4]. Abnormal amino-acid sequences have now been shown for a number of genetic hæmoglobin diseases[5–8] and could therefore serve to indicate successful transfer of genetic information.

Megaloblasts were chosen because they are arrested at a primitive stage and might be susceptible to the influence of genetic material during maturation. Sickle-cell anæmia was chosen as a source of the nucleoproteins because it is the most readily available source of the genetic hæmoglobin diseases.

Marrow was aspirated from patients with sickle-cell anæmia, the DNA extracted with 2 *M* sodium chloride, deproteinized with deoxycholate and isolated by precipitation with 95 per cent ethanol. The final product was a highly viscous material containing 5–10 per cent ribonucleic acid and a similar amount of protein in addition to the DNA. No further attempt was made to remove these substances because of their potential contribution to transforming activity. This material was dialysed against 0.1 *M* sodium chloride and 0.05 *M* sodium citrate in the cold for 24 hr. and incubated with megaloblastic bone marrow. Each incubation mixture contained 10 ml. of sternal marrow aspirated from a patient with megaloblastic anæmia and 10 ml. of *S*-15 tissue culture fluid[9] which was supplemented by 5 mgm. heparin, 0.50 mgm. folinic acid, 0.10 mgm. vitamin B_{12}, 20,000 units penicillin and 0.12 µc. (80 µgm.) of ferrous citrate (iron-59)

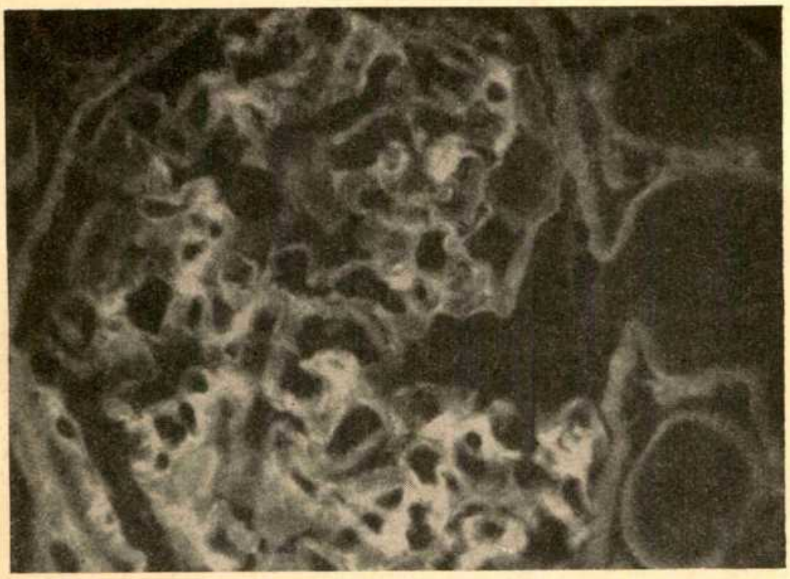

Fig. 1. Fluorescent photomicrograph of a human kidney stained *in vitro* with sheep anti-human placenta fluorescein conjugates. The basement membranes of glomeruli, Bowman's capsule and tubules show specific apple-green fluorescence which appears white in the photograph. Note the tubule opening into Bowman's space. Cellular structures do not stain. Identical results were obtained with sheep anti-human glomerular basement membrane fluorescein conjugates. (× *c.* 525)

rabbit anti-rat glomeruli serum stained connective tissue structures in various rat organs and was nephrotoxic for rats. Evidently nephrotoxic antibodies are part of the localizing antibodies. Since direct bioassay is not possible in man, the demonstration of heterologous antibodies to human placenta which collect in human glomeruli would prove that human placenta and glomeruli share closely related antigens. Such localizing antibodies might be nephrotoxic.

Since little is known about the relationship of antigens in human placenta and kidney, this investigation was undertaken to determine if human placental antigens were present in human kidney and where such antigens were located, using the immunofluorescent technique of Coons[4].

Human glomerular basement membrane was prepared as previously described[5]. The membrane was suspended in isotonic saline to a concentration of about 80 mgm. per ml. A 1 : 1 water-in-oil emulsion was made with Freund's adjuvant consisting of 85 ml. 'Bayol *F*', 15 ml. 'Arlacel *A*' and 200 mgm. *Mycobacterium butyricum* (Difco).

A human placenta was obtained shortly after birth, freed from membranes and washed grossly free of blood. Minced placenta and isotonic saline were mixed in a Waring blender for several minutes and then incorporated into Freund's adjuvant. Additional saline was added until the final concentration of placenta in the emulsion was about 1 gm./6 ml.

About 6 c.c. of the human glomerular basement membrane emulsion and 30 c.c. of the placental emulsion were injected into individual sheep by intramuscular, intradermal and subcutaneous routes every 2 weeks. Each sheep was bled to death one week after the fifth injection. The sera were removed and stored in the deep freeze (− 15° C.) until needed.

The globulin fractions were separated from the sera by half-saturation with ammonium sulphate or the cold alcohol fractionation method of Deutsch[6]. The γ-globulin was conjugated to fluorescein isothiocyanate according to Riggs's method[7].

Human kidney tissues were obtained soon after autopsy or from surgical specimens. Human placentas were obtained immediately after birth. Portions of tissue were frozen in isopentane cooled by a mixture of dry ice and acetone, and sections 4 microns thick were cut in a cryostat. The fluorescein - conjugated antisera were passed through a 'Dowex' resin column and then absorbed with 150 mgm. of acetone-dried mouse liver powder per c.c. of conjugated serum. In addition, 1 part of antiserum was absorbed with 2 parts of oxylated whole human blood.

The absorbed antisera were then used directly to stain the tissue sections and careful controls were used as described by Coons[4]. The slides were examined with a Leitz microscope fluorescence unit and permanent photographic records were made.

Fluorescein-labelled sheep antibodies to human glomerular basement membrane or human placenta stained identical connective tissue structures in the kidney. These structures may be defined as the basement membranes of glomeruli, tubules, Bowman's capsules and intertubular capillaries. Certain extracellular structures in the media and adventitia of arteries were also stained. The stained structures in the media of arteries might correspond to the basement membranes of smooth muscle cells according to Gersh[8]. The structures in the adventitia of arteries might represent irregularly condensed ground substance.

Fluorescein-labelled sheep antibodies to human placenta and human glomerular basement membrane stained the placenta in similar manner. Specific staining was diffusely present throughout the entire connective tissue core of the villus with heavy con-concentration in blood vessel walls and in the subsyncytial cell layer.

Cellular structures in the kidney and placenta did not show specific staining. None of the control sections showed the specific apple-green fluorescence. An interesting incidental finding was the observation that autofluorescent internal and external laminæ were not seen in placental blood vessels encountered even though some were of large size.

The results of these preliminary experiments indicate clearly that human placenta and human glomerular basement membrane share a closely related antigen or group of antigens. Further, that the placenta contains an antigen or group of antigens which is present in various connective tissue structures of the kidney.

The chemical nature of the antigen (or antigens) is unknown. The areas that stain most intensely in the placenta and kidney with fluorescein-conjugates are also periodic acid–Schiff positive. Mature collagen is reported not to stain in rats[3] and man[9], using anti-glomeruli fluorescent conjugates. It would seem unlikely that collagen fibrils are the antigen involved in the present investigation.

In general, nephrotoxic sera have been shown to stain many connective tissue structures of many

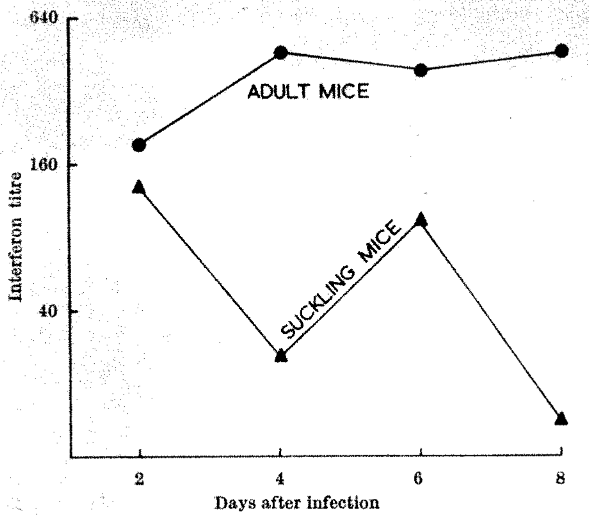

Fig. 3. Interferon titres in lung extracts of adult and suckling mice at various times after infection. Pools of three lungs tested at day indicated, mean titres of three experiments. Titres shown as the reciprocal of the dilution of lung extract causing 50 per cent reduction in the virus plaque counts

The lungs taken at each time-interval were pooled and extracts prepared. The amount of saline used for the extracts was adjusted according to the weight of the lungs. The material was tested for the amount of virus present (ID_{50} titrated in chick embryos) and interferon content (plaque reduction test in mouse embryo fibroblast monolayers infected with approx. 100 plaque-forming units of encephalomyocarditis virus[5]). Four such experiments were carried out, and the combined results are presented in Figs. 2 and 3. As can be seen from the graphs, the virus titres were higher in suckling mice, and interferon content lower than in the infected adults. No significant differences in interferon content were seen at the early stage of infection but differences became evident towards the end of the infectious process—during recovery.

As was indicated earlier, the speed of virus elimination as an indicator of the recovery process in adult mice might have been influenced by locally produced antibody. In the lungs of the infected suckling mice no antibodies were found, and there is suggestive evidence from the experiments described here that the recovery process was influenced by the amount of interferon produced. The lower content of interferon in the lungs of the infected suckling mice could be responsible for both the higher virus titres during the course of infection and the longer persistence of virus.

Differences in the course of both naturally and experimentally induced viral infections in young as compared with adult animals have been repeatedly described in the past and with few exceptions[10] they indicated that younger animals were more susceptible to infection with many different viruses[11-22].

Acquired resistance of growing animals to certain neurotropic viruses in the absence of humoral antibodies or previous exposure to these viruses was described as early as in 1936 by P. K. Olitsky *et al.*[11]. The factors which might have influenced the refractory state of adult animals were considered obscure.

Very young mice showed a higher susceptibility to rabies virus infection than adult mice, but only when fixed virus was used[19]. In this connexion it is worth mentioning a recent finding that attenuated virus is a better producer of interferon than virulent virus[23].

It has been found that during maturation of the embryo there is a steady increase in the sensitivity of the cells to interferon and in their ability to produce interferon[6]. The present results suggest that this process may continue during post-embryonic life and that this may be a factor governing the response to virus infection in young animals.

CLOSELY RELATED ANTIGENS IN HUMAN PLACENTA AND KIDNEY

By Dr. RAYMOND WILLIAM STEBLAY

Department of Obstetrics and Gynecology, University of Chicago

ONE of the many theories of the etiology of toxæmias of pregnancy maintains that maternal antibodies formed against placental antigens may damage maternal glomeruli. In order to support this hypothesis, it would be desirable to demonstrate that human placenta and human glomerular basement membrane contain closely related antigens; and secondly, that the placenta has a mechanism by which these closely related placental antigens might vary sufficiently to 'appear' foreign to the mother so as to provide an antigenic stimulus. The antibodies formed against this antigenic stimulus could be expected to collect in the human glomerular basement membrane and initiate glomerular damage. This hypothesis is based on the premise that in order for antibodies to damage tissues, they would first have to be present in the affected tissues. Such antibodies could properly be called autoantibodies and this mechanism an autoimmune mechanism.

Seegal reported that the rat[1] and dog[2] placenta and kidney contain nephrotoxic antigens in common. Cruickshank and Hill[3] reported fluorescein-labelled

It seems that the feeding of the meal part of each of these diets in the form of a gruel enabled a large proportion of it, if not all, to by-pass the rumen. This was associated with markedly better utilization of dietary protein, presumably brought about mainly by a more efficient use of dietary energy

INFLUENCE OF AGE OF MICE ON THE RECOVERY FROM EXPERIMENTAL SENDAI VIRUS INFECTION

Dr. LEON SAWICKI*
National Institute for Medical Research, Mill Hill, London, N.W 7

THE view is now prevalent that Sendai virus[1] (*Myxovirus parainfluenzae* 1)[2] persists in laboratory mice mainly in the Far East Attempts to produce a persistent infection in mice, carried out by C H Andrewes and me[3], were unsuccessful Intranasal infection occasionally caused lethal pneumonia, but among animals which recovered it was observed that adult mice eliminated the virus much earlier than the suckling ones. This indicated that the recovery process in very young mice might be handicapped

In order to study this further 4 weeks old mice were inoculated intranasally with 0 05 ml and suckling mice infected during the 1st day of life with 0 01 ml of allantoic fluid containing 100 EID_{50}/ml of Sendai virus Five adult mice along with 5 sucklings were killed 4 and 6 days and daily from 8 to 15 days after infection The presence of virus was checked by sub-inoculation of the lung extracts from individual mice into 11-day-old chick embryos The results of this experiment are shown in Table 1 In adult mice, virus was no longer recovered after the 8th day of infection, whereas in suckling mice virus was detectable up to 14 days, the titres being high up to the 9th day after infection (ID_{50} tests in pieces of chick chorioallantoic membrane[4]) In the same experiment sera of adult mice were tested at various times after infection for the presence of hæmagglutination inhibition antibodies No antibody was found Lung extracts of infected adult mice contained small amounts of viral antibody as measured by the hæmagglutination inhibition test from the 8th day after infection (Fig 1) No antibodies were found in lung extracts of the suckling mice up to the 15th day after infection. While one cannot exclude the possibility that local hæmagglutination inhibition antibodies might have influenced the elimination of virus in adult mice, it is difficult to support this explanation in the case of suckling mice which eliminated virus by the 15th day after infection despite the complete lack of any detectable hæmagglutination inhibition antibody in their lungs

Table 1 PERSISTENCE OF VIRUS IN ADULT AND SUCKLING MICE AT VARIOUS TIMES AFTER INFECTION
Numerator number of mouse lungs yielding virus. Denominator number of mouse lungs tested

Mice	Days after infection									
	4	6	8	9	10	11	12	13	14	15
Adult	5/5	5/5	4/5	0/5	0/5	0/5	0/5	0/5	0/5	0/5
Suckling	5/5	5/5	5/5	5/5	5/5	3/5	1/5	4/5	1/5	0/5

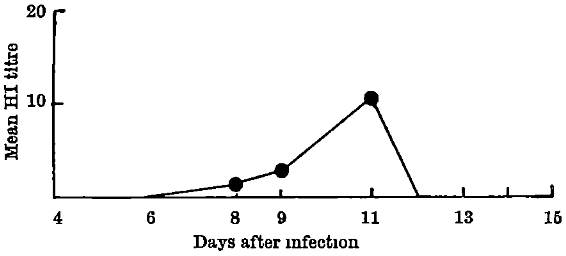

Fig. 1 Hæmagglutination inhibition (HI) antibodies in lung extracts of adult mice at various times after infection Mean titres of five lungs individually tested

There are reports which indicate that an important role in recovery from primary viral infections may be played by interferon[5-8] In this connexion it is of interest that recovery from viral infection can occur in the absence of any antibody formation, for example, in the chick embryo[7], or in the presence of only traces of antibody, for example, in patients with hypogammaglobulinæmia[9]

Experiments were therefore set up to compare interferon production in experimentally infected adult and suckling mice Three animals of each group were killed 2, 4, 6 and 8 days after infection

Table 1 PERCENTAGE COMPOSITION OF THE DIETS

	Diet *X*	Diet *Y*
Ingredients		
Hay (crude protein, 6 99 per cent of dry matter, crude fibre, 35 5 per cent of dry matter)	25	25
Spray-dried, separated-milk powder	20	—
Fatted milk powder*	—	40
Rolled barley	30	7
Barley meal	10	10
White fishmeal	15	18

* The fatted milk powder was prepared by the homogenization of crude red palm oil with liquid separated-milk, followed by spray drying in a commercial plant to produce a powder containing 50 per cent of fat

utilization of those carbohydrates which are capable of being well assimilated by monogastric digestion It seems likely that even when calves are receiving hay, and behaving as functional ruminants, the feeding of the concentrate part of their diet as a gruel enables this food to bypass the rumen If the carbohydrates are then more efficiently utilized than when fed dry this should increase the available energy of the diet, and thereby improve nitrogen retention[2] It was therefore decided to examine the comparative effects of wet and dry feeding on the nitrogen balance of calves

Four ruminating Ayrshire bull calves, approximately 14 weeks old and housed in metabolism crates, were used for the investigation Two diets were made up as shown in Table 1, the hay being kept separate from the other components Chlortetracycline (17 mgm per lb of diet) and supplements of trace minerals and vitamins A, D_3, E and the B complex were included Each diet was allocated to two calves In all the balance periods (periods 7, 8 and 9) the daily allowance of meal for each calf (1,050 gm) was given in two equal feeds, at 9 a m and 5 p m The daily allowance of chopped hay (350 gm) was given immediately after the morning feed For the first and last parts of the experiment (periods 7 and 9), the 525 gm of meal for each feed was mixed with two litres of warm water and bucket-fed immediately During period 8, the meal was fed dry, followed by two litres of warm water per calf Each balance period of eight days was preceded by a preliminary period of six days The collection and analysis of fæces and urine were carried out as previously described[3], except that fæcal nitrogen determinations were made on composite wet samples at the end of each period

The effects of dry and wet feeding on the mode of absorption of the carbohydrates were studied at the end of periods 8 and 9 by measuring the changes in reducing sugars of the blood following a normal meal, and also one containing in addition 200 gm glucose The reducing sugars were determined by King's method[4] on samples of blood taken at 0, 1½, 3, 6 and 8 hr after feeding

It is evident from the results in Table 2 that the retention of nitrogen by each calf was markedly lower with dry feeding than with wet feeding Since dry feeding was associated with a somewhat greater digestibility of the crude protein, the differences in nitrogen retention were due to differences in the extent to which absorbed nitrogen was retained It should also be noted that the efficiency of nitrogen retention was much higher on diet *Y* (the high-fat diet) than on diet *X*, with each method of feeding, suggesting that lack of available dietary energy was at all times an important factor in limiting the retention of nitrogen

From the changes in reducing sugars of the blood 1½ hr after feeding the respective meals without added glucose (Table 2), it is evident that all four calves showed appreciable rises following wet feeding compared with much smaller changes after dry feeding This difference in response to wet and dry feeding supports the view that wet feeding enables a considerable proportion of the food to pass directly into the abomasum, whereas dry feeding is associated with entry of the food into the rumen, with subsequent fermentation Lactose has previously been shown to be capable of producing an appreciable rise in reducing sugars of the blood[5], and since the single feed of each diet would supply an estimated 70 gm of lactose, some of the response must have come from this source

Further evidence is provided by the results obtained when 200 gm of glucose were added to the food Calves 1, 2 and 3 showed little or no response to the added glucose with dry feeding, but very marked responses with wet feeding In the case of calf 4, although there was an appreciable rise in blood glucose following dry feeding, this was greatly increased with wet feeding

It is of interest to note the greater rises in blood sugar on the high-fat diet since this has also been observed in studies of human nutrition[6]

Table 2 COMPOSITION AND DIGESTIBILITY OF DIETS, NITROGEN BALANCE, AND BLOOD REDUCING SUGARS

Composition of diets (dry matter basis)	Diet *X*						Diet *Y*					
Crude protein (per cent)	25 7						24 3

* Mean of initial and final weight for each period

occur and the lizard's tail habitually regenerates rather a makeshift for the original structure. This may adequately serve its biological purpose, however, and the whole variety in degree of convergence is consistent with a natural selection basis.

It must also be remembered that the power of regeneration is as ancient as that of ontogenesis itself, that asexual reproduction and other morphogenetic processes grade into that of regenesis[2], and that ontogenesis and regenesis have evolved together, step by step, throughout their long history. It would perhaps be surprising to find anything but quite close convergence between them. It also seems probable that in general the same genes control both. In arthropods abnormalities such as the regeneration of a leg in place of an antenna are paralleled by similar abnormalities of ontogenesis, and these are known to be determined in typical Mendelian fashion. Regeneration probably can be regarded as just a special case of what Wigglesworth[3] has called 'developmental polymorphism', the insect embryo produces a first set of legs and other organs, and then a new, imaginal set is produced at metamorphosis. There are also other pieces of evidence that ontogenesis and regenesis are components of a common mechanism[2], and we can scarcely regard the convergence between them as special evidence in favour of final causation. This does not affect the possibility that they, and all biological phenomena, show more general evidence of the operation of final causes, but most biologists believe that natural selection could have produced the apparent purposefulness in the many interesting cases discussed by E. S. Russell and others. Among these, internal homœostatic mechanisms do figure, of course, if not as frequently as external anatomical features.

Final causation as usually understood is perhaps a problem purely for the philosopher, since it is scarcely amenable to the scientific approach. At the same time biologists must be as much concerned as philosophers in the problem of reconciling their respective approaches to the acquisition of knowledge. This problem stems largely from the differences between the axiomatic premises of the two approaches and, so long as these remain, it is not reasonable to expect any ultimate integration of their views. By axiomatic law final causation, as usually understood, is ruled out of the scientific court and no amount of subsequent pleading can bring it in again. It may be a reality, but it cannot be tested experimentally.

Some biologists might regard natural selection as somewhat in the position of a final cause[2] in the sense that it has the appearance of acting in the manner of a *deus ex machina* on the fundamental processes governed by efficient causes. It has the virtue of being a cause which can be investigated by observation and experiment. For this very reason it is not a final cause in the usual sense but may prove to be all we need to seek. It has been pointed out[4] that the conception of natural selection is just another way of saying that at every time and place only the viable systems survive: few would object to the view that the final cause of life is its viability. Survival of the viable, and extinction of all other, systems may be generalized into the principle that what actually occurs in each spatio-temporal context is the most probable event in that context. The viable automatically behave as though directed towards the goal of survival. In the behaviour of the higher animals this has become very purposeful in appearance. The anticipatory character of ethological responses and of ontogenesis certainly appears purposive to an observer but it should be remembered that these activities are largely recapitulatory of past experiences, of the individual and the species respectively, and are not purposive aims at entirely novel objectives.

The 'most probable' conception of final causation, originating entirely from within a biological outlook, could ultimately provide a coherent and comprehensive account of evolution which might meet the requirements of philosophers. At the same time it discourages the idea that there is necessarily a sharp psychophysical dualism in the phenomenon of life. Spilsbury believes that this dualism also corresponds to one between subjective and objective experience, but it is perhaps debatable if our subjective experience is anything beyond an objective study of ourselves.

Dr. Spilsbury raises a number of minor issues which many biologists might wish to take up, but it would be wrong to obscure his main thesis by pursuing them here. There are also one or two puzzling passages, such as the apparent contradiction between the two properties demanded of any prospective change in the genetic control of regeneration, and some unguarded phrases such as "organic causation", "expedite future survival" and " 'inner' and 'outer' aspects of behaviour".

COMPARATIVE EFFECTS OF WET AND DRY FEEDING ON THE UTILIZATION OF PROTEIN BY CALVES

By A. M. RAVEN and K. L. ROBINSON

Chemical Research Division, Ministry of Agriculture for Northern Ireland, and Agricultural Chemistry Department, Queen's University, Belfast

It is generally accepted that when liquid milk is fed to young calves it by-passes the rumen and reticulum, by means of the œsophageal groove[1], and enters directly into the abomasum. This permits the food to undergo monogastric digestion. The recent trend towards the early weaning of calves by a system involving dry feeding of concentrate meals is associated with the early development of a functional rumen. However, fermentation in the rumen is a relatively inefficient process, which penalizes the line between development and behaviour is a fine one If behaviour is not fully describable in spectator-language, the same may be true for development (This does not imply that developmental processes may be conscious We learn from self-consciousness that some vital functions are directed at future ends It does not follow that all future-directed processes are conscious Consciousness may reveal one facet of organic functioning without constituting its essence) This possibility cannot be excluded, so long as the problem of development, as at present conceived—how the 'genetic code' is 'made flesh' and conditions the psycho-physical attributes of the adult—remains unsolved In principle, the attempt to define ontogenetic precursors or rudiments of mind seems not less justified that the corresponding attempt in phylogeny (Not on the ground that ontogeny repeats phylogeny, but on the ground that we should seek to connect later states of a system with earlier ones) A conceptual bridge is yet to be built between the human zygote, considered as a biochemical system, and the purposiveness of the adult man, if the latter is to be explained partly as a consequence of the former. It is plausible to look for this bridge in the intervening processes of development, and especially in the interpretation of the 'anticipatory'[4] appearance of development, the pre-functional elaboration of parts destined to become an integrated system of functional organs in the adult. No theory of development can be deemed satisfying which does not offer an explanation of this progressive realization of functions, just as no theory of the neuro-physiology of behaviour is satisfying which does not explain how the progressive realization of a future end-state is possible (In neither case can selection theory provide a substitute for an analysis of the concurrent causes of this central feature of development and behaviour

That there has been selection for mechanisms which expedite future survival does not tell us what these mechanisms are. Disregard of this led to the nineteenth-century error of substituting speculations about phylogenies for analysis of ontogenies Development theory has been retarded first by being viewed exclusively through Darwinian spectacles, and more recently through Mendelian ones. Mendelism abstracted from the forward thrust of developmental processes, and concentrated on correlating starting-points with end-points, parental phenotypes with filial phenotypes Necessarily, the concept of the gene arrived at by these methods is inadequate as a basis for development theory This abstractive tendency of genetics is re-inforced by modern concentration on the genetics of micro-organisms, with their relatively simple ontogenies It is possible in the future that development theory will influence conceptions of genetics and evolution as deeply as it has hitherto come under their influence) The temporal organization of vital processes, which makes meaningless any analysis of the organism-at-an-instant, presents similar patterns and problems for all the life sciences Information theory has made familiar the notion that organisms store up information from the past, both in their brains and their germ-cells Possibly a similar generalization will prove fruitful with respect to the forward direction of organic processes, which often proceed as though organisms possessed information about the future, and may produce an adaptive end-result even in circumstances different from those encountered in the (phylogenetic) past—as when a normal adult develops from the fusion of two amphibian eggs Unless some generalized concept can be made to cover all instances of future-directed functioning, it is hard to see how the reference to the future involved in conscious anticipation can be made intelligible in relation to its ontogenetic and phylogenetic history, and one possible ideal of theoretical biology will have to be abandoned

Dr Spilsbury renders a general service in bridging the gulf between philosophy and biology, and a special service to biology in focusing attention on regeneration as a critical test case of the ability of the Darwinian theory to explain the mode of evolution. His suggestion that the genetic determination of regenesis (the process of regeneration) may be independent of that of normal ontogenesis also must interest biologists Can we be sure that natural selection is a factor powerful enough to establish perfect convergence between the paths of these two morphogenetic processes, and also to maintain the perfection of the convergence throughout a long evolutionary series of changes in the final, adult form ? As Spilsbury has further pointed out in correspondence, selection in favour of regenerative ability seems to be much weaker than that in favour of normal ontogenesis since, while the latter is inevitably demanded, the former is only possibly evoked in each individual life Normal development is a *sine qua non* for propagation by the individual whereas often regeneration is called for only late in the reproductive phase of life Consequently even if natural selection provides an adequate explanation of the evolution of normal ontogenesis, it may not be adequate to explain the perfect convergence by regenesis. By the same token, however, if it should prove a sufficient explanation of the latter then we need have little doubt that it can explain the evolution of ontogenesis and of biological adaptations in general

An exact mathematical approach, by Fisher and Haldane in particular, has emphasized how small an advantage may have selective value for the individual, and survival value for the species Successful regeneration, even if called for in only a small percentage of individuals, provided it enables them to make a further small contribution to the size of the next generation may make just the difference between an assured survival and an inevitable extinction for the species. This is true even on the assumption that regenerative power is equal in all the individuals of a species, but there is also likely to be selection differentially in favour of individuals combining a high regenerative power with other advantageous characteristics Moreover, regeneration is not so rare in the field[1] as implied above and this is further supported by a recent census on populations of three species of *Planaria* Between 25 and 50 per cent of the individuals of the different species were in process of regeneration at that moment, so that each individual is likely to be challenged several times during its life. Selection in favour of regenerative ability therefore is stronger than appears at first sight

The perfection of the convergence between ontogenesis and regenesis should not be overstressed It is usually extremely good, but mistakes sometimes

EVOLUTION OF REGENERATION, AND ITS POSSIBLE BEARING ON PHILOSOPHY

NEEDHAM[1] has recently criticized the view of Morgan and others that the distribution of regenerative capacities is not closely correlated with their adaptive value This criticism, if accepted, can be used to answer one objection to the Neo-Darwinian interpretation of regeneration and its evolution Other problems remain Regeneration, when adaptive, is a secondary adaptation; it is the adaptation of an adaptive embryonic sequence to the special conditions under which regeneration occurs, the relation between the primary and secondary adaptation being one of likeness in the final developmental product, and often of unlikeness in the processes of development. A spectacular instance is the regeneration of the urodele lens In cases such as this, it may fairly be assumed that regenerative processes are adaptive only if they restore a close copy of the part lost This imposes a stringent condition for the selection of regenerative mutants, if the capacity for regeneration has evolved in this way.

In the present state of ignorance about the genetic basis of regeneration, the following alternative assumptions appear open to orthodox evolutionists The first alternative assumes that different or partly different groups of genes are active in regeneration and embryonic development, each set embodying different instructions for, for example, lens-making On the other assumption, the same genes are involved in both cases, causing different developmental processes in different circumstances

The first alternative implies a highly improbable convergence in the evolution of embryonic and regenerative development, with close correspondence, at different evolutionary stages, between the end-products of independently varying gene assemblies Such an ontogenetic convergence, maintained throughout an evolutionary series, would be less comprehensible, on the assumption of random genetic change, than convergent evolution between different species, where the resemblances are less exact

On the alternative assumption, the evolution of regeneration may be ascribed to selection for genetic changes which facilitate double-track development by the same genetic determinants Such genetic changes are required (1) to leave unchanged former developmental tracks, at least with respect to their end-product, (2) to initiate new tracks, the usefulness of which depends on their leading to the same end-state as the old tracks The same paradox arises here as on the assumption of independent genetic controls for embryonic and regenerative development the paradox of ascribing the replication of identical structures, through different developmental processes, throughout an evolutionary sequence, to random genetic changes which have been selected It is legitimate to doubt whether so exact a coincidence of results could have come about in this way There seems to be no evidence for the occurrence of equifinal regenerative mutations, having the developmental effects outlined above

Equifinality or end-invariance, attained through variable precurrent events, is a pervasive property of life and the products of life[2], from the cellular to the social and technological grades of organization. Its elucidation would probably be of philosophical significance, as offering the lure of the long-awaited solution of the mind/body problem, and of a general concept of organic causation connecting final with efficient causes The split between these may be linked with the dualism of spectator and participant Activities which, to a spectator, appear determined by past causes, to their participants, appear aimed at future ends While in atomic physics it has become necessary to emphasize the impact of the observer on the observed, in evolutionary biology it is necessary to note the impact, mediated by a common descent, of the processes studied on their students' ways of thinking about them Awareness of this impact implies an almost existentialist sense of personal involvement in evolutionary processes, out of which has somehow surprisingly sprung the human capacity for concern over evolution, past and future. What may be called a detached spectator's view of evolution, the *post factum* assessment of evolution as determined by efficient causes, makes a coherent and comprehensive theory of evolution impossible, so long as the relation between these efficient causes and the development of the capacity for future-directed action remains a mystery. (Darwin's famous personification of natural selection, as the never off-duty scrutineer of variation, vividly reflects the view that the course of evolution has been determined by factors in principle observable by a sufficiently acute and unremitting onlooker. Another symptom of the spectator's point of view, in Darwin and some modern writers on evolution, is the disproportionate emphasis on external adaptations to specific features of the environment, and the comparative neglect of the integrative and regulative capacities of the organism in development and self-maintenance)

All historical studies of past life are liable to be conducted from a spectator's point of view, including the study of human history One reason for this is that the working back from present to past, characteristic of all historical inference, reverses the natural order of events, and obstructs their evaluation from past to future, from the participants' point of view

From our present grasp of the mechanisms of evolution, we can no more derive the evolution of purpose than from our present understanding of cerebral mechanisms we can derive either the 'inner' or 'outer' aspects of behaviour Consequently, claims that Neo-Darwinism provides a coherent synthesis of all the known relevant facts are baseless The interest and challenge of equifinality lie in its hint that we do not have to resign ourselves to this incoherence, and that the struggle for a unitary conception of unconscious organic processes and mental processes, within an evolutionary framework, may not be vain Possibly these processes are not merely analogous, with respect to equifinality, but even homologous, in the sense of having a common evolutionary origin There seems no compelling reason why the search for homologues of mind should be restricted to the field of behaviour As Sinnott[3] and others have pointed out, the dividing both the earliest and the established pattern of the disease, the patient with a skin blemish can watch, if he wishes, the growth of a curable cutaneous cancer Carcinoma of the lung is different from both, it produces symptoms (that is, something of which the patient complains) as a by-product of its naturally hidden position and will produce them when quite small should it simultaneously involve a blood vessel and a small peripheral bronchus, when blood-stained sputum may be expectorated, but commonly is measured in centimetres and produces the first symptoms due to remote spread The size of a tumour, its duration or its clinical accessibility or visibility are not in themselves important in prognosis The overriding factor is our knowledge based on experience of the natural history of each type of tumour For example, the prognosis in the case of squamous cell carcinoma depends on which organ it primarily involves, and extrapolation from one species to another must be done with extreme caution Nevertheless, any basic studies of that neglected field—animal pathology—are most welcome A complete understanding of tumour behaviour must include such knowledge, hence the work of Silver and Cater on the treatment of spontaneous tumours in animals by radiotherapy or by chemotherapeutic agents offers a little hope that research workers have not forgotten the value of comparative investigations

Prof Bullough's group at Birkbeck College continue work on the diurnal mitotic rhythm of normal mouse epidermis and conclude that it is due to the hour-by-hour variations in the ability of prepared cells to enter division and not to hour-by-hour variations in the numbers of cells preparing to divide, that the ability of cells to enter division depends on variations in the secretion-rate of adrenalin, and that these variations in turn depend on a degree of stress felt by the animal, stress being higher when a mouse is awake than when it is asleep On this fascinating work one could build, with little imagination, a hypothesis accounting for human cancer as, in part, a psychological disorder (This has been attempted in the past with no convincing success, but a careful psychosomatic approach to human cancer is worth while)

With the chemotherapeutic agents at present available, one of the practical problems is that of delivering a dose of a drug which will result in the death of tumour cells, but which is not lethal to the patient, drugs with a greater specificity towards tumours are being developed while, at the same time, techniques using existing drugs aim at better localization Where the tumour is in a limb, this becomes a fairly simple matter of perfusion, where the growth is widely disseminated, the urgent problem is to preserve a bone marrow which can regenerate after severe depression or even total death of bone marrow following administration of chemotherapeutic agents Techniques vary from using living fœtal marrow from a fœtal tissue bank or the storage of the patient's own aspirated marrow for later re-injection, to an ingenious technique reported by Starr in New South Wales, where the patient's aspirated marrow is injected into a drill-hole in the tibia after a tourniquet is applied, only to be released after an otherwise lethal intravenous dose of cytotoxic drug has become fixed or eliminated, in 1–3 hr

At Makerere College, Uganda, animal tumours are investigated by exfoliative cytology, many tumour cells being studied to greater advantage when flattened on glass slides than in paraffin sections In the case of the transmissible (venereal) tumour of the dog it has been found that the round cells infiltrating the lesions are plasma cells, frequently binucleate with a 'mirror image' pattern In enzootic hæmaturia of cattle (a disease characterized by progression of papilloma of the bladder to carcinoma) investigations have confirmed the findings of some Turkish pathologists, and support a viral origin of the condition These cytological observations show that the bovine urinary bladder has secretory function Well-known virus diseases of animals—canine distemper and infectious pneumonitis of cats—are now being investigated by this rapid method of study

As for many years past, the report provides plenty of evidence of the widespread use of physical techniques involving radiation and radioisotopes, this year there is evidence of the rapid extension of diagnostic and research uses of the latter in remote parts of the world But there is little which is sufficiently novel to require mention. Hospital physicists, perennially suffering from erratic radiation background, will be interested to know that, at the Royal Cancer Hospital, an attempt is being made to build a low-background room on a small outlay of money. Chalk in paper bags, 2 ft thick, is being used for this, the inner surface of the room being lined with ½-in aged lead. Another development which looks like being of practical importance is taking place at the Middlesex Hospital, where the radiation-induced destruction of the fluorescence of quinine sulphate is being investigated as a method of measuring γ- and X-ray dosage The results suggest that doses of 10 rads or even less can be estimated with good accuracy; it will be interesting to hear further of this work.

Among radiotherapeutic developments note should be taken of the Royal Cancer Hospital's use of solid sources which have been made radioactive by neutron bombardment These include a Souttar's tube, for treatment of the œsophagus, made of silver-plated nickel wire containing a core of gold, and two laryngectomy tube applicators of copper-nickel alloy, giving, after activation, a dose-rate of the order of 200 rads/hr The Department of Radiotherapeutics at Cambridge has continued its efforts, noted here last year, to use the selective uptake of tritiated 'Synkavit' in cancer as a therapeutic measure Information is given on methods of administration, dosage, and means for increasing selective concentration Information is also given on the degree of selective uptake in various types of tumour-tissue as compared with bone-marrow Investigations, subject to the usual limitations, have been made on patients and the results are so far inconclusive On the other hand, parallel investigations on animals which are also reported look promising A similar line of investigation is reported from the Sheffield Regional Radiotherapy Centre, where the selective uptake of radioactive zinc-labelled hæmatoporphyrin has been investigated with encouraging results, however, no details are given

The Leeds centre is making a new approach to the study of bone mineralization Attempts are being made to relate the transmission through bone of radiations of markedly different quality to the quantity of calcified bone lying in the path of the beam Thulium-170 and cæsium-137 have been used in this work which, if successful, will make it possible to study bone mineralization by *in vivo* methods

I HIEGER
A L LEVENE

the problem seems to have been entirely overlooked by the legislators There is, therefore, a renewed interest in compounds of the flavone and isoflavone series described later in this report"

Salaman and co-workers find that new-born mice are highly sensitive to carcinogens, after one year, of 26 mice of the '101' strain which had received 30μ of dimethylbenzanthracene neo-natally, 9 developed leukæmia, 25 lung adenoma, 7 skin papilloma and 16 papillomas of the forestomach

Cunningham and colleagues at the Royal College of Surgeons have been studying cytologically the process of liver cancer induction by dimethylaminoazobenzene using a technique of section cutting which permits the life-like preservation of cellular structures in that mitochondria, free lipid, lipid-protein bonds and dehydrogenases are retained intact, the tissue being sectioned at − 25° after cooling to − 70°

Orr has been continuing his work on the chemical induction of mammary cancer in the mouse, such tumours did not develop in female mice of the *C*57*B*1 strain after painting the skin with dimethylbenzanthracene (DMBA)—a standard technique—but if the females were made pseudo-pregnant by being caged with vasectomized males and then painted with DMBA, 21 out of 29 mice developed breast tumours due to the added stimulus from progesterone in pseudo-pregnancy

Orr and Mandl find that senile virgin rats are very liable to spontaneous mammary tumours, of 69 such females aged between 600 and 1,200 days, 34 (49 per cent) showed macroscopic fibroadenomata, while a parallel series of 46 female rats used for breeding had an incidence of only 4 per cent mammary tumours "It is tentatively suggested in the light of these observations that continuous secretion of œstrogen by virgin animals, uninterrupted by phases of progesterone secretion during pregnancy, stimulates the anterior pituitary The œstrogen-stimulated pituitary secretes appreciable quantities of luteotrophin even before it becomes enlarged, at the same time output of other gonadotrophins decreases The secretion of luteotrophin would account for both the mammary hyperplasia and the presence of excessively large corpora lutea Absence of corpora lutea could be explained by insufficiency of LH with failure of rupture of Graafian follicles"

Baldwin, at Nottingham, finds that a commercially available motor-engine oil additive is highly carcinogenic for mouse skin, it consists of a mixture of compounds which include lead naphthenate, carbon tetrachloride, 1,1,1,-trichloroethane and a petroleum oil base, the indications are that the active factor is present in the oil base

King, Hughes and Louis at Melbourne, in interesting work on the fluorescein conjugate staining of tissues, state "The studies of the last four years have been continued and extended In addition to serum globulins, serum albumin has been conjugated with fluorescein and rhodamine The differential avidity of the dye for serum albumin as opposed to globulins has been confirmed In addition, sera from species other than those previously examined have been investigated with similar results, normal tissues of all species studied stained but malignant tissues failed to stain

"Tissues grown in tissue culture show the staining and fluorescence characteristic of normal tissues for the first three days By the fourth day staining becomes patchy and subsequently no staining can be obtained, that is, after the fourth day the culture shows the same staining characteristics as malignant tissue This conforms with observations made on re-introduction of such tissues into the original animal or one of the same species, when they grow in the same manner as true neoplasms"

In Melbourne also, Trautner and Coats have been using an ingenious technique in the study of species immunity to cancer, mouse ascites carcinoma cells were suspended in nutrient fluid in 'Perspex' chambers (0 1 ml) fitted with non-reactive 'Millipore' filters of pore size 0 6–0 3μ "Attempts to transplant the tumour directly from the mouse to either the rat or the guinea pig were uniformly unsuccessful " When the chambers were inserted intraperitoneally in rats or guinea pigs the growth of the mouse cancer cells was at least as prolific as in mice "It was found that growth of the tumour in the rats and guinea pigs was as good as or better than it had been in mice, and the day-by-day growth characteristics were studied It would appear that the tumour-host hostility evident on direct inoculation was dependent on cell-to-cell contact between tumour cells and the host "

Studies in geographical pathology come from the University College of North Wales ("Cancer Incidence in Relation to Trace Elements in Soil and Plants"), Makerere College, Uganda ("Cancer in African Children") and the University of Bristol

Statistical data from the Bristol Tumour Registry show that under the age of 40 the English incidence of bone sarcoma is similar to Norwegian figures After that age the tumour is much more common in south-west England, due largely but not entirely to the frequency of Paget's disease of bone in the English population, but not in the Norwegian population Except in those subject to Paget's disease the tumour has a monomodal age incidence curve, the English incidence showing a typical bimodal curve

Paget's disease (osteitis deformans), probably the commonest non-traumatic disease of bone seen in an orthopædic department, was described in some detail in 1876 by Sir James Paget It has been described in animals, too, and is an etiological feature of canine osteogenic sarcoma, where it is much more common in some breeds than in others The author of this study is clearly aware of the need to combine a knowledge of geographical pathology with genetics, comparative pathology and basic clinical observation in the elucidation of the most fundamental aspect of any disease —its natural history

A report on a clinico-pathological investigation of cancer of the cervix uteri concludes that (1) beyond a certain dosage (irradiation) range the physical modalities of irradiation do not significantly alter the cure-rate for cancer of the cervix, (2) the clinical extent of the disease and such quantitative biological characters as Broder's grade and size of tumour foci have a significant influence on the five-year survival-rate, (3) among the qualitative biological characters the histological type of the tumour and its ability to respond initially with an increase in differentiation profoundly affect the cure-rate, (4) systemic factors, of yet unknown character, can control the growth of persisting cancers for long periods

The same, or similar, methods of treatment, unmodified in essentials for perhaps 20 years or more, are in use in hospitals throughout Britain, and naturally their reports read much the same At present the clinician subscribes to earlier diagnosis as well as better surgery, irradiation or chemotherapy as one of the principal means of improving results Not in all cases is this meaningful, the patient with an enlarged lymph node due to lymphosarcoma has

Of particular scientific interest is the large programme of work now in progress on the quantitative aspects of fire in structures, both real and idealized. A particular object of this is to establish scaling laws for rate of burning, size of flames and the spread of fire by heat transmission from them, and the disposal of smoke by ventilation.

The statistical inquiries, as always, are interesting, and this year include reference to the incidence of fire in post-war houses, fires caused electrically, and aircraft crash incidents. Tests have been carried out on the relative effectiveness of audible warning devices in traffic, from which the traditional fire bell emerges rather badly. Preliminary experiments on the use of a gas turbine as an inert gas generator for extinguishing fires in large building spaces have given encouraging results. Fire-resistance testing of building materials, work on the prevention or mitigation of gas and dust explosions, and a number of other projects have been continued.

J. H. BURGOYNE

PROGRESS OF CANCER RESEARCH

THE annual report of the British Empire Cancer Campaign continues to expand year by year; the thirty-eighth edition* is a massive book of nearly 800 pages, the scientists working either wholly or partly under the ægis of the Campaign number nearly 1,500, and a million pounds was spent on research in 1960.

Some idea of the trends of cancer research, as described in the report, can be suggested by breaking down, into subject-matter and class, the total of papers published in 1960 by these investigators and comparing the resulting catalogue with that for 1950; the papers will, of course, represent the work more or less completed before 1960 rather than the present progress, but the main lines will undoubtedly remain substantially the same (Table 1). The table shows that in the ten years the trend has been to increase the volume of work on biochemical themes at the expense of carcinogenesis and radiobiology, and that the immunological and statistical approach is attracting more research.

Only a little of the large amount of research work detailed in the report can be referred to here. One of the most interesting investigations continues to be on the Gross leukæmia-inducing virus and the related polyoma virus. Miller confirms that removal of the thymus in *C3Hf/GS* mice at 3–4 months after they have been neo-natally inoculated with the Gross virus prevents the development of lymphocytic leukæmia which otherwise appears in 100 per cent of such inoculated mice. Grafting isogenic thymus into the thymectomized mice restores the growth potentiality of leukæmia. *C3H* mice which had been made tolerant to tissue from *Ak* mice at birth were inoculated with normal *Ak* thymus and became leukæmic; transplantation tests showed that the lymphocytic neoplasm arose from host cells and not from the inoculated *Ak* cells, thus demonstrating that a non-cellular factor from *Ak* thymus is a necessary component in the origin of this lymphocytic leukæmia.

C3H mice injected at birth with the Gross virus were later given a lethal dose of radiation and protected with normal isogenic marrow from untreated mice; most of the injected mice developed leukæmia, and tests with protecting cells carrying a marker chromosome indicated that the leukæmogenic virus is not only radio-resistant but is also resistant to any immune attack that might have been exerted by the protective marrow cells, and therefore there is not much hope of treating leukæmias of viral origin by total-body irradiation and marrow replacement.

Ambrose and colleagues, in experiments on normal and malignant cells grown *in vitro*, conclude that "The characteristic properties of the tumour cells so far suggested in the present studies are therefore as follows: (1) the tumour cell membranes show reduced mutual adhesiveness as compared with normal cells; (2) several lipases and phospholipases are more toxic for tumour cells than for normal cells and the tumour cells are also more sensitive to lipid in the medium, suggesting that more exposed lipid is present on the tumour cell membrane; (3) the structure of the tumour cell involves a less basic protein than the normal cell, suggesting a more acidic micro-climate at the cell surface, in agreement with the electrophoretic studies indicating an increased negative surface charge".

The possible cancer risks attached to the use of œstrogen implantation in cattle and poultry is the subject of a report by Sir Charles Dodds. "There has been a new interest in the alleged carcinogenic action of œstrogens during the past year. The widespread use of stilboestrol and hexoestrol in agriculture has generally been approved by governments. Stilboestrol implantation in poultry for the purpose of caponisation has become almost universal and it is also estimated that a very large percentage of meat produced in the North American continent has been produced under the influence of stilboestrol, hexoestrol or some similar substance. There has been a change recently in the administrative outlook in the North American continent on the use of these substances and at the present time, in America, their use has been banned by what is known as the Delaney Amendment to an Act in the F.D.A. This whole question is being looked into and we have been particularly interested in attempts to assess the intake of œstrogens in a normal diet. This aspect of

Pp. xxxix–lviii+792. (London: British Empire Cancer Campaign, 1961.)

two similar receivers, the front one of which is exposed to the radiation. The target consists of a massive copper disk 4.5 cm. in diameter and 0.5 cm. thick to ensure temperature uniformity. Thermocouples are attached at a number of points in order to average the rise in temperature. The electrical heating element is cemented to the front disk on the side exposed to the radiation. The cycle of operations and the practice carried out in the Laboratory for the calibration of working-standard thermopiles against the Guild radiometer with a radiation source, consisting of a 1,000-W. tungsten lamp operated at a colour temperature of 2,850° K., together with water filter and heat-absorbing glass to absorb radiation of a wave-length longer than 1μ, are explained in detail.

The second booklet, No. 24 (ref. 2), is concerned with photometric standards and the unit of light. The development of light sources from the early nineteenth century and the evolution of the present primary standard, with the internationally accepted unit of luminous intensity, the candela, are discussed, followed by a detailed description of the procedures carried out at the National Physical Laboratory with regard to the arrangement of the primary standard, and calibration of secondary standards of luminous intensity and luminous flux. Finally, the present international situation with regard to intercomparisons of photometric scales is reviewed, and a table is given showing the relative magnitudes of the candela (2,042° K.) as found in the most recent determinations (up to 1957) at various national laboratories. The monograph can be recommended as a comprehensive and instructive statement of photometric standards and light sources, and should be of value to all concerned with illumination. S. Weintroub

GEOLOGY OF BROWN CLEE HILL AND THE ADJACENT AREA

*The Old Red Sandstone of Brown Clee Hill and the Adjacent Area**, recently issued by the British Museum (Natural History), is an important paper as it deals with a classic area in which is displayed the most complete sequence of Old Red deposits of the Anglo-Welsh development. In the first quarter of the century Wickham King established a general stratigraphical succession for that development, which he based to a large extent on his findings in the Brown Clee district, but his supporting palæontological evidence was too meagre and scattered to provide really convincing fossil zones. At that time too many of the forms had been inadequately described or named from fragments. King's work, however, generated a stimulus that has led to a revolution in our knowledge of the British Old Red ostracoderm faunas. This has been the result of systematic collecting and accurate description. The latter we owe chiefly to the senior author, Dr. E. I. White, and Part 2 of the present paper is his latest contribution to the subject. While our knowledge of the fossils has been gradually accumulating, the palæontologist has had, to a great extent, to rely on King's stratigraphical conclusions, which were not always based on reliable mapping.

In the present case the two junior authors have presented an excellent map based on accurate 6-in. survey and elaborate collecting, which have enabled them to determine the range of the fossils with considerable accuracy. For the Downtonian Series, they have taken advantage of much recent palæontological work, and the zones for this series can now be regarded as well established, and their evidence as merely confirming conclusions reached previously in this and other areas. But for the desperately barren Dittonian and Clee Series, their painstaking field-work has supplied Dr. White with material, by which broad zones can now be defined with some exactness.

Part 1, devoted to the stratigraphy, includes interesting discussions concerning the geographical conditions governing sedimentation, the ecology of the fossiliferous 'pockets', the so-called *Psammosteus* Limestone (which has never yielded a fossil, let alone a *Psammosteus*), and foreign pebbles in the conglomerates, but its main significance is the correlation of the fossils with the stratal succession, and the determination of the range of each important species. A valuable feature is a list of more than a hundred localities with the fauna discovered at each.

Part 2 is descriptive of a number of new species and varieties illustrated by 60 text figures and 16 plates. Of particular value are the new forms discovered by the authors and others in the Clee Series and in the unconformable upper Old Red beds (the Farlow Sandstone Series). L. J. Wills

FIRE RESEARCH 1960

The recently issued annual report of the Joint Fire Research Organization* records the bringing into use, during 1960, of new buildings providing 30,000 sq. ft. of permanent floor area for the continued prosecution of fire research (see *Nature*, 189, 105, 1961).

Among the many investigations described, that which focused attention on the behaviour in draughts of oil heaters of the drip-feed radiant type has doubtless aroused the greatest public interest. The relatively new and unique wind-tunnel facilities of the Fire Research Station permitted an expeditious study of this problem, followed, within the year under review, by the publication of a report and a new British Standard and, finally, by the introduction of appropriate legislation.

showed but a poor increase in yield (its merits were made clear in later trials under improved conditions). A belief had therefore grown up that the attainable yield of rain-grown cotton in the area was decidedly lower than that for other African territories.

Rainfall (total and effective) appeared to be the dominating factor for yield, and experiments were made during 1957–59 to assess its influence. From meteorological records and observations, 40 in. was deduced as the expected (1 : 1 chance) annual rainfall, 27·4 in. of which would come after July 1, and under local conditions a crop of cotton would need about 25 in. of rain in the growing season if growth was not to be limited by soil moisture (July 1 is recommended as the sowing date for cotton, as the earliest which allows food crops to be planted first). What happens to rain after reaching the soil and how control of this influences yield were the primary issues in the field experiments.

Surface 'capping' through heavy rain, to which the local soils are specially prone, was shown to be largely controllable by timely hoeing and by mulching, entry of rain into the soil being thus greatly increased. The land is ridged for cotton and other crops, and it was found that here, as elsewhere, water conservation could be improved by 'tying' the ridges with small bunds at intervals along the furrows. In dry years this considerably increased yield but depressed it in wet years. These effects were clearly interpreted by soil–moisture profiles.

The effects of varying degrees of these controls having thus been measured, field trials were arranged, having in mind steps which could be fitted into peasant practice. A light mulching, in the furrow bottoms only, proved effective, and by slitting the furrow bottom and working a small amount of mulch into the slit the effect was enhanced. Tying alternate ridges only worked well, and avoided yield depression through standing water in wet years. Groundnut shell, dead grass and chopped *Sorghum* stalks made good mulches, the shell being best. By preparing the land for sowing at the onset of the rains, instead of just before sowing, which is local practice, cotton yields were raised by 15 to 20 per cent in two trials. Increased penetration and retention of rain had evidently been secured. Good response to fertilizers was obtained where tied ridges and mulch were also used.

The practical inference was clear—fertilizers, insecticidal protection, improved varieties and other betterments are repaid only when water conservation is amply ensured and this is practicable at peasant husbandry level. To drive the lesson home, cotton was grown on a half-acre plot for four years running in which rainfall was 55, 35, 42 and 43 in. Yields were all of the order of 2,000 lb. of seed cotton an acre, which is good for rain-grown cotton anywhere and excellent in comparison with any other part of Africa. Moreover, picking was ended by Christmas whereas it dawdled on for another 2–3 months on other plots.

This successful husbandry investigation is of more than local and immediate value. It is part of the widespread studies of rainfall, soil moisture and crop water needs carried out by the Empire Cotton Growing Corporation. The basic work is done at its Central Research Station, Namulonge, Uganda. All this work deals not with cotton alone but also in conjunction with the customary food crops of cotton growers. Agriculture in general is thus benefited in cotton-producing countries. Moreover, the practical problems centring on rainfall are becoming so defined and resolved as to enable their deeper, physiological study to be effectively opened up. Plant breeding, also, gains a clearer sense of direction.

F. L. ENGLEDOW

RADIOMETRIC AND PHOTOMETRIC STANDARDS

TWO recent publications in the series *Notes on Applied Science* of the National Physical Laboratory, Teddington, illustrate some of the activities of the Light Division of the Laboratory.

No. 23 in the series[1], *Radiometric Standards and Measurements*, by E. J. Gillham, deals with the methods used at the Laboratory for the measurement of ultra-violet, visible and infra-red radiation. The contents consist of three main sections devoted to the measurement of total radiation, the measurement of monochromatic radiation, and the absolute measurement of radiation, respectively. Total radiation is usually more intense than monochromatic radiation and therefore can be measured more easily, but the total energy content of a beam of radiation is often of less practical significance. An instrument for measuring total radiation must be equally sensitive to radiation at all wave-lengths, and the only means of converting radiation into another form of energy with predictable efficiency over the whole wave-length range is by absorption at a blackened surface, that is, to use a thermal detector. Fortunately, blacks with an absorption factor of 95 per cent or more over the whole spectral range of interest are available, and consequently thermal detectors with an error due to selectivity of not more than 2 or 3 per cent can be obtained. The type of thermal detector commonly used is the thermopile, and in the booklet the Moll thermopile, which has stable characteristics and which forms a very useful working standard for measuring radiation or for calibration of other radiation detectors, is described in some detail. A set of six Moll thermopiles is maintained at the National Physical Laboratory for calibration purposes. The methods used for the intercomparison of thermopiles and for the accurate measurement of the selectivity of a thermopile using a Callender radio-balance and three different sources of radiation are discussed.

To illustrate the problems encountered in the measurement of monochromatic radiation a description is given of a routine test undertaken at the Laboratory to determine the special sensitivity of a photoemissive cell, in the 0·25–0·7μ wave-length range. The optical arrangements and apparatus required for the measurement of the spectral sensitivity, and also the absolute sensitivity of the photocell, are given. For the absolute measurement of radiation a thermal detector in which the target is provided with a resistance element or other means for supplying a measurable amount of electrical power is recommended. At the National Physical Laboratory the absolute radiometer used is the Guild drift radiometer. It is of the compensated type with

ULTRASTRUCTURAL ALTERATIONS DURING THE CRABTREE EFFECT IN ROUS SARCOMA CELLS

By Prof. ALVIN S. LEVINE, RUTH PETRAITIS and JAMES GREEN*

Departments of Microbiology and Anatomy,
Indiana University School of Medicine,
Indianapolis

ELECTRON microscopic studies show that glucose selectively alters the microstructures of Rous sarcoma cells and that the cellular alterations observed could account for suppression of respiration[1] (Crabtree effect). The mechanism of glucose suppression of respiration of tumour cells has generally been approached through biochemical investigations[2]. Work in this laboratory indicates that glucose utilization *per se* does not depress uptake of oxygen. It was reported that increasing the concentration of glucose in the medium containing normal tissue will increase glucose utilization to a rate comparable with that of tumour tissue without suppressing respiration[3,4]. This preliminary report shows that when Rous sarcoma virus-induced tumours of the chorioallantoic membrane are excised from embryonated chicken eggs and incubated *in vitro* in the presence of glucose the cells undergo microstructural changes. Degeneration of mitochondria is observed. This effect of glucose on mitochondria of Rous sarcoma cells is similar to that reported by Merker *et al.* for Ehrlich ascites tumour cells[5]. Changes in the nucleus and endoplasmic reticulum of Rous sarcoma cells were also observed. These changes were not observed when Rous sarcoma was incubated in medium without glucose or in normal chorioallantoic membrane incubated in the presence or absence of glucose.

Standard lot *CT* 842 of Rous sarcoma virus was obtained from Dr. W. Ray Bryan and used for inducing tumours of the chorioallantoic membrane as previously reported[3,4]. Rous sarcoma was dissected free of non-tumorous tissue and sliced with a Stadie–Riggs hand microtome. Tissue slices were incubated under aseptic conditions in a Warburg flask in a final volume of 2 ml. with modified Hanks's balanced salt solution in the absence of added bicarbonate, and without phenol red indicator. The *p*H was adjusted to 7·6 with dibasic phosphate (*M*/15). The glucose concentration used was 5·5 µmoles/ml. Control flasks were without glucose.

After 12 hr. incubation at 37° C. tissues incubated with and without glucose were removed from the flask and immediately fixed in 1 per cent buffered osmium tetroxide[6] for 1 hr. at room temperature. The fixed tissue was embedded according to standard procedures in a 4:1 mixture of butyl and methyl methacrylates. Polymerization was carried out overnight at room temperature under an ultra-violet lamp. Sections were made with a Porter–Blum microtome equipped with glass knives.

Oxygen uptake was determined manometrically on tissue slices of tumour and chorioallantoic membrane. Results are reported on the average hourly rate of oxygen uptake during the 12th to the 16th hr. of in-

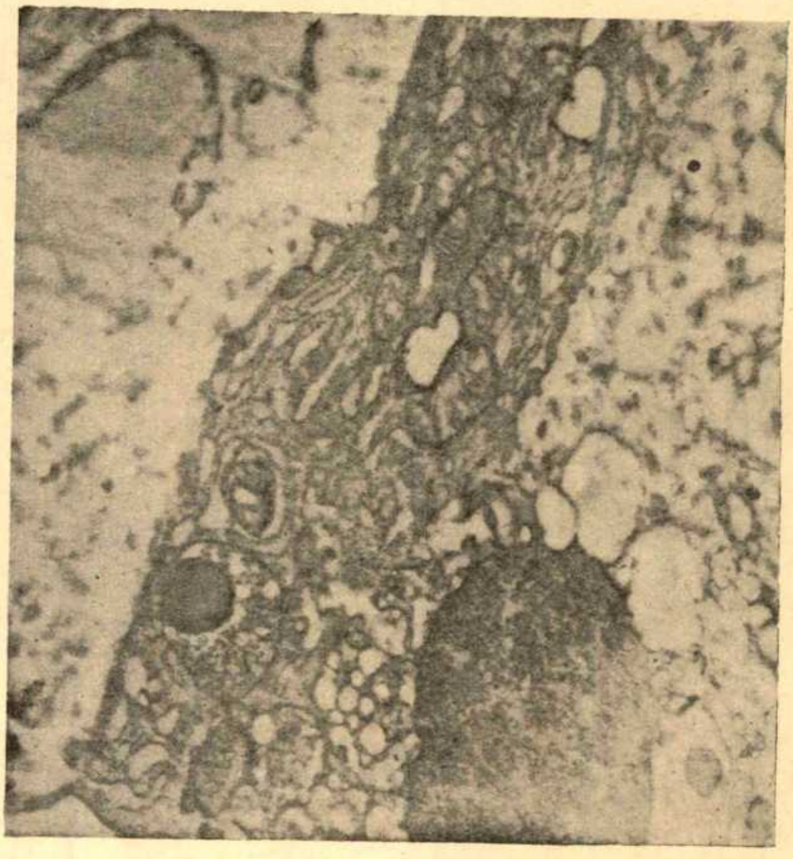

Fig. 1. Electron micrograph showing detail of a cross-section of a Rous sarcoma virus-induced tumour of the chorioallantoic membrane. Slices of tumour tissue were incubated in modified Hanks's balanced salt solution without glucose for 12 hr. at 37° C. The tissue was fixed in 1 per cent buffered osmium tetroxide and embedded in a 4:1 mixture of butyl and methyl methacrylates. The flattened surface cell shows mitochondria and cristæ and a well-delineated endoplasmic reticulum. Many vacuoles are present in the lower mesodermal cell and its nucleus shows a homogeneous composition. (× *c.* 16,500)

---

* Present address: Department of Anatomy, University of Missouri, Columbia, Missouri.

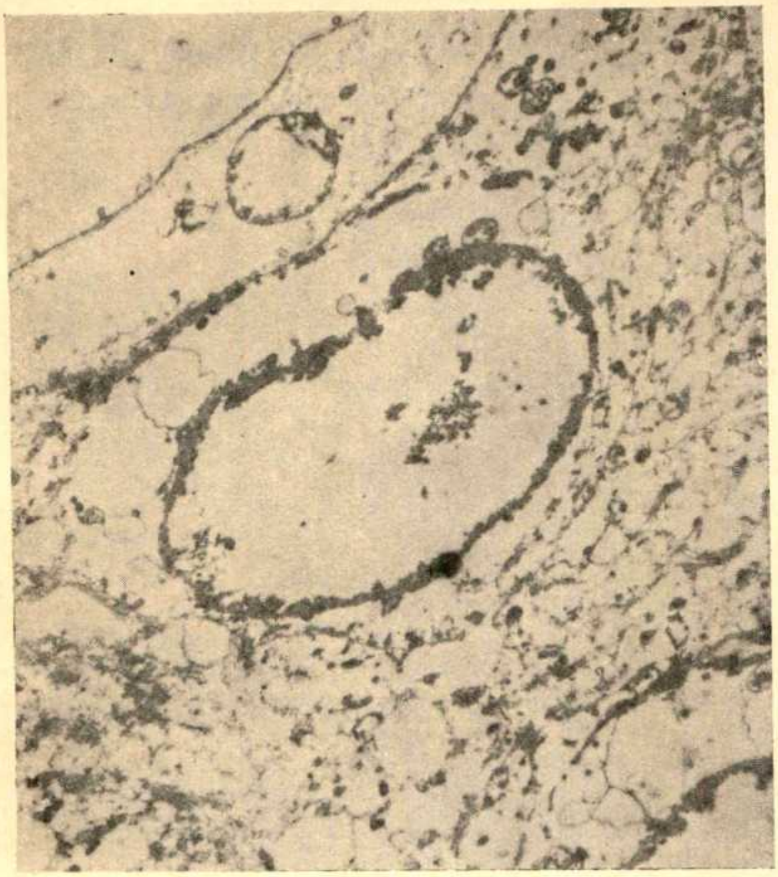

Fig. 2. Electron micrograph showing a cross-section of Rous sarcoma virus-induced tumour of the chorioallantoic membrane. Slices of tumour tissue were incubated in a modified Hanks's balanced salt solution with 5·5 μmoles/ml. of glucose for 12 hr. at 37° C. The tissue was fixed in 1 per cent buffered osmium tetroxide and embedded in a 4:1 mixture of butyl and methyl methacrylates. The flattened surface cell and mesodermal cell give the appearance of being 'leached out'. The degeneration of microstructures is evidenced by marginal clumping along the nuclear membrane, no well-defined endoplasmic reticulum, and no well-defined cristæ in what appears to be the remains of mitochondria. (× *c*. 11,000)

cubation to show the physiological state of the tissues at the time samples were taken for electron microscopic studies. Results given in Table 1 were determined on tissue slices from the same tumour viewed by electron microscopy (Figs. 1 and 2). Respiration results on chorioallantoic membrane are similarly reported for sections from the same membranes viewed by electron microscopy.

Slices of Rous sarcoma which had been incubated 12 hr. in Hanks's balanced salt solution were examined by electron microscopy (RCA-*EMU*-2). Well-delineated microstructures were observed (Fig. 1). The cells selected show a cross-section of the tumour with regard to the surface of the chorioallantoic membrane. It is not known if the flattened surface cell is ectodermal or endodermal, but distinct mitochondria with cristæ are observable as well as a defined endoplasmic reticulum. The nucleus of the mesodermal cell has a homogeneous composition, but the cytoplasm shows greater vacuolation. Representative sections of other mesodermal cells show well-formed mitochondria even though the increased numbers of vacuoles in mesodermal cells distort the endoplasmic reticulum. A comparable section (Fig. 2) shows a cross-section of tumour slices which had been incubated for 12 hr. with glucose. The flattened surface cell as well as the mesodermal cell give a 'leached out' appearance. There is no defined endoplasmic reticulum, and the only evidence of mitochondria may be cross-sections seen in the mesodermal cell giving a degenerate appearance. The nuclei show marginal clumping and the 'leached out' appearance seen in the cytoplasm. More than 200 sections of tumour tissue that had been incubated in glucose were made and examined. No well-formed mitochondria were seen. The 'leached out' appearance of the cytoplasm and nucleus was present in all cells observed.

Table 1. AVERAGE HOURLY RATE OF RESPIRATION DURING 12–16 HR.

Tissue	Medium	Oxygen uptake (μl./mgm. dry tissue/hr.)
Rous tumour	BSS	5·2
	BSS + glucose 5·5 μmoles/ml.	1·8
Chorioallantoic membrane	BSS	6·3
	BSS + glucose 5·5 μmoles/ml.	6·1

Direct method of Warburg 2 ml. final volume of reaction chamber at 37° C. Tissue weight range, 3–5 mgm. dry weight. Chorioallantoic membrane was from a 16-day-old embryonated egg. BSS, modified Hanks's balanced salt solution.

Comparable sections of normal chorioallantoic membrane, that do not give a Crabtree effect when incubated with glucose, appeared normal when examined under the electron microscope. In chorioallantoic membrane mitochondria were seen with well-defined cristæ, nuclei appeared homogeneous in composition, and the endoplasmic reticular system was well delineated.

It seems reasonable to propose that the physiological effect of glucose on Rous sarcoma respiration (Crabtree effect) may be a secondary result of the effect of glucose on the functional structures of the cell rather than a direct biochemical competitive inhibition. Damage to the cristæ of mitochondria results in 'leaching out' of enzymes and co-factors and respiration is interrupted[7]. It is proposed that glucose selectively induces damage to the mitochondria of Rous sarcoma cells and this may be the lesion of the Crabtree effect.

This work was supported in part by research grants: *C*–4692, of the National Cancer Institute, U.S. Public Health Service, and *E*–212, of the American Cancer Society, Inc. Grateful acknowledgment is made to the Indiana Elks' Association for support of the electron microscope work of this study.

EFFECTS OF 2-DIETHYLAMINOETHYL 2,2-DIPHENYLPENTANOATE (SKF 525A) ON INSECTICIDAL POTENCY

By P. S. HEWLETT, C J LLOYD and ANGELA N BATES

Pest Infestation Laboratory, Slough

2-DIETHYLAMINOETHYL 2,2-diphenylpentanoate (SKF 525*A*) is well known to prolong the actions of a variety of drugs in mammals[1], and we have therefore investigated the effects of the compound on the toxicity to insects of pyrethrins and other insecticides, comparing its effects with those of the pyrethrin synergist 'piperonyl butoxide' (PB)[2,3] SKF 525*A* has been administered to mammals in the form of its water-soluble hydrochloride, but when injected the hydrochloride proved inconveniently toxic to the test insects, and if applied externally could be expected to penetrate only slowly through the insect cuticle, hence we dosed the insects externally with SKF 525*A* in the form of the free base, which, like PB, was then non-toxic at the doses used

In a series of qualitative tests, lesser mealworm beetles, *Alphitobius laevigatus* (F), were dosed topically between the hind coxæ[4] with a solution of SKF 525*A* or PB, and 5–10 min. later with a solution of insecticide on the neck[5]. Separating the applications reduced the risk of chemical reaction between the basic SKF 525*A* and those insecticides that were acidic, before they had penetrated into the insect 7 µgm. of SKF 525*A* or PB were applied in 0 07 µl. of solution in refined (odourless) kerosene, and an appropriate dose of insecticide in 0 025 µl of solution in a heavier refined petroleum oil, Shell 'Risella 17'. Applications of insecticide without SKF 525*A* or PB were made comparably, with a dose of oil solvent on the other site Use of the two different oil solvents enabled the two techniques of dosage to be used in conjunction In additional qualitative tests, houseflies, *Musca domestica* L , were dosed topically[4] with pyrethrins or malathion, mixed with SKF 525*A* or PB, in solution in refined kerosene Effects were determined by percentage of beetles paralysed 4 days after dosage (approximating to final mortality) and percentage of flies dead 24 hr after dosage The results, shown in Table 1, indicate a joint-action spectrum for SKF 525*A* qualitatively similar to that for PB, reduction by PB of the insecticidal activity of malathion in flies has been noted previously[6]

Table 1 EFFECTS OF SKF 525*A* AND PB ON THE TOXICITIES OF CERTAIN INSECTICIDES

Insecticide	*A laevigatus*		*M domestica*	
	SFK 525*A*	PB	SKF 525*A*	PB
Pyrethrins	+	+	+	+
Allethrin	+	+		
Barthrin	+	+		
Malathion	(–)	–	–	–
2-*n*-Valeryl 1,3-indandione	+	(+)		
2-*sec*butyl 4,6-dinitrophenol	0	0		
DDT	0	0		
γ-BHC	0	0		
Dieldrin	0	0		

+, Considerable synergism, (+), slight synergism, 0, no effect, (–), slight antagonism, –, considerable antagonism

The synergistic effects of SKF 525*A* and PB on the pyrethrins were compared quantitatively The synergist was used in mixture with the pyrethrins, in solutions in refined kerosene The volume was 0 07 µl. per beetle, applied between the hind coxæ[4], and 0 05 and 0·10 µl per male and female fly respectively, applied dorsally on the thorax[4] Factors of synergism[3,7] were determined, each the ratio of the ED_{50} for pyrethrins in the absence of synergist to that in the presence of synergist at 10 times the dose of pyrethrins With SKF 525*A* the factor was 1·8 for the beetles and 2 5 for the flies; with PB the factor was 3 2 for the beetles and 15 for the flies SKF 525*A* was less synergistic than PB

Neither 2,2-diphenylpentanoic acid nor 2-diethylaminoethanol affected the toxicity of pyrethrins Other congeners of SKF 525*A* are being investigated

In mammals SKF 525*A* depresses the metabolism, especially oxidative metabolism, of numerous drugs, thereby increasing[1] or decreasing[8] their effectiveness according as the metabolic products are more or less active than the drugs themselves In the present work SKF 525*A* depressed the effect of malathion, which is oxidized in the cockroach, *Periplaneta americana*, to the more insecticidal malaoxon[9] O'Brien[10] mentions that SKF 525*A* failed to reduce the action on the cockroach and the housefly of certain organo-phosphorus insecticides with more insecticidal oxidation products, but does not state the conditions in his experiments In the present work SKF 525*A* was found to increase the effectiveness of pyrethrins, which, like related pyrethroids, are metabolized in insects to less insecticidal compounds not as yet identified, though chromatographic evidence[11] indicates that they could be oxidation products. The influence of PB on the toxicities was qualitatively similar to that of SKF 525*A* Thus the findings reported here are in general accord with other evidence[12] that PB and other 3,4-methylenedioxyphenyl compounds synergize pyrethrins in insects by depressing oxidative detoxification

In mammals SKF 525*A* depresses drug metabolism brought about by the liver microsomes[1], a scheme has been put forward[10] to account for the apparently low specificity of the enzyme systems involved The present results suggest that there may be in insects systems analogous to those inhibited by SKF 525*A* in the liver microsomes of mammals

We are indebted to the Smith Kline and French Research Institute, Welwyn Garden City, for a sample of SKF 525*A*

BLUE-GREEN ALGAE

Growth

It is well known that many species of algae fail to thrive in simple inorganic media and may be cultured with greater ease in the presence of ill-defined organic materials such as soil extract[1,2]. These observations have promoted the suggestion that such algae may have requirements for growth factors, especially since many species are now known to be unable to synthesize certain vitamins essential to their metabolism[3]. In an earlier discussion of this question, however, Gerloff *et al.*[4] have directed attention to the fact that, in general, the addition of organic solutions of unknown composition has never been found to be absolutely essential for growth. They conclude that stimulation to growth under these conditions may be ascribed to the physiological condition of the algae rather than to the provision of some essential vitamin-like substance. Nevertheless, their statement that it is unlikely that any members of the Cyanophyta will be found to exhibit a requirement for vitamins has been shown to be in error in at least one instance by Pintner and Provasoli[5], who have discovered an absolute requirement for vitamin B_{12} by *Phormidium persicinum*. It is particularly interesting to note that several species of algae have been found not to thrive in the absence of other micro-organisms. In fact, Schramm[6] found himself unable to induce growth of zoospores and zygospores of *Vaucheria*, *Oedogonium* and *Spirogyra* in bacteria-free conditions. Among the Cyanophyta, Fogg[7] records the common observation that *Gloeotrichia natans* fails to thrive as well in pure as in impure culture. Findings such as these seem to support the assertion of Pringsheim[1] that "multiplication is often harder to achieve than isolation from bacteria and other unwanted micro-organisms". Similar experience and difficulties and the absence of more precise information led me to undertake the present work, the chief results of which are described here.

In isolating bacteria-free cultures of blue-green algae from rich soils of tropical northern Australia[8,9], observations were made with an unidentified species of *Nostoc* which agree closely with those for *Gloeotrichia natans* recorded by Fogg[7]. Growth of the alga in impure culture was clearly superior to that in pure culture. The stimulatory effect was found to be due to a species of the stalked bacterium *Caulobacter* which was prominent among the contaminants. When the two organisms were grown together in the light in a suitable nitrogen-free mineral medium, considerably greater amounts of nitrogen were fixed than by the alga alone under otherwise identical conditions. These results are shown in Table 1. It will be seen that, whereas 9·64 mgm nitrogen were fixed by the alga in pure culture, 17·43 mgm were fixed in the presence of the bacterium. In each case, a notable proportion of the nitrogen fixed was released into the culture solution. Separate tests showed that the *Caulobacter* is unable to fix nitrogen in pure culture. At the present time, there is no evidence to indicate that the stalk has any special function in the association comparable with the attachments shown by Houwink[10] to cells of *Bacillus*, although it has been found that the structure reaches maximal development in the presence of the alga and does not appear to be formed on media such as meat extract agar. It is worth noting that stalked organisms of the same genus have been found commonly in impure cultures of other blue-green algae from widely separate parts of Australia.

Table 1. NITROGEN FIXED (MGM.) BY *Nostoc* ALONE AND IN ASSOCIATION WITH *Caulobacter* (KJELDAHL ANALYSES)

	Nostoc	*Nostoc* with *Caulobacter*
Cells	6·14	12·46
Culture solution	3·50	4·97
Total	9·64	17·43

To obtain greater understanding of the relationship, the stages in the growth cycle of the alga were followed in Petri dish culture. It was observed that hormogonia, on formation, move away from the colony margin and then undergo a series of reciprocal movements along the path first followed, this activity culminating in a sudden arching of the originally straight filament. At this stage, motility is lost and the individual cells begin to enlarge and divide in such a manner that the developing trichome becomes more and more contorted. Terminal and intercalary heterocysts become apparent, the latter being formed at fairly regular intervals along the trichome. The alga has never been observed to produce akinetes. Continued growth results in the formation of a roughly spherical trichome mass 0·1–0·2 mm. or more in diameter, from the interior of which a second generation of hormogonia emerges.

If single migrating hormogonia are transferred to fresh medium, their movements commonly cease, trichome formation begins almost immediately and the cycle of growth continues normally for at least a while. Frequently, however, the hormogonia either lose their pigmentation and die without further development or continue their normal growth and die at some later stage, often before the emergence of the second generation of hormogonia. Even when colonies 20–30 mm. in diameter are produced from a single hormogone, they are invariably pale in colour and thinly formed, and made up in large part of colourless and apparently non-viable trichomes. The capacity of hormogonia to continue developing has been found to be closely associated with the light history of individual colonies. Failure of hormogonia to develop on transfer may be induced most readily by frequent sub-culture under conditions of continuous and relatively intense illumination.

When small numbers of nitrogen-starved *Caulobacter* cells are added to single transferred hormogonia, growth is always more rapid than in the absence of the bacteria and is never accompanied by the death of the alga. Colonies produced in this way are larger, thicker and more densely pigmented than pure cultures and do not contain the colourless trichomes so characteristic of the latter.

Initially, it was supposed that some essential organic nutrilite might have been lacking in the absence of the bacterium, although this seemed rather unlikely in view of the fact that at least reasonably normal development was often observed to occur in pure culture as already described. None the less, the possibility was investigated. It was found that the incorporation in the basal nitrogen-free mineral medium of materials such as yeast extract, casein hydrolysate as well as the individual vitamins thiamine, biotin and B_{12} and a range of single amino-acids were without effect. Without exception, single hormogonia transferred to the supplemented media failed to develop. Similar results were obtained when low concentrations of ammonia or nitrate ions were supplied. Even when growth took place in the presence of inorganic nitrogen, it was not superior to that in control plates.

Later, it was discovered that the addition of one or two drops of a 1 p.p.m solution of indole-3-acetic acid was capable of effecting the recovery of bacteria-free hormogonia degenerated to the colourless condition preceding death Accordingly, tests were conducted using *Avena* coleoptile sections in an attempt to detect growth-stimulating hormones in cultures of the alga and the bacterium It was found that a highly significant increase in the length of coleoptile sections occurred in the presence of *Caulobacter* cells compared with controls A similar response was recorded with sections in contact with a reasonably healthy pure culture of the alga grown for three weeks at only 12 ft.-candles and also with 18-hr cultures, associated with *Caulobacter*, from which hormogonia were beginning to emerge at about 100 ft.-candles. In pure cultures more than 4 weeks old and grown at relatively high light intensities between 500 and 600 ft -candles, the growth of coleoptile sections was significantly inhibited.

From these observations, there seems little doubt that, in some way, substances with hormone properties are necessary to enable the alga to achieve normal development Here, attention is directed to a recent investigation in which Lazaroff and Vishniac[11] have concluded that *Nostoc muscorum A*, too, is dependent on a 'morphogenetic substance' to complete its normal cycle of growth With *N muscorum*, however, the substance is never limiting under normal conditions of cultivation in the light Abnormal growth is exhibited only when the alga is incubated in the dark with a suitable source of carbon

The inhibiting influence of older cultures on the growth of coleoptile sections is of interest That the effect might have been caused by excess hormone seems improbable It is known that auxin and indole-3-acetic acid are inactivated by light. Granick[12] has directed attention to the particularly destructive effect of blue light on auxin. In this connexion, it is relevant to note that the warm-white fluorescent lights used in the present work emit strongly in this region and have been found harmful to several species of chlorophycean algae by Algeus[13] A more plausible explanation for the results is suggested by the separate observation by Algeus[2] that the oxidation products of indole-3-acetic acid are inhibitory to growth However, it should not be overlooked that Stewart *et al* [14] have found a precursor of auxin in radishes that exerts a similar effect

Whatever the nature of the inhibitory substance or substances, it is possibly correct to assume that normal development of the *Nostoc* in question is dependent on the balance existing from time to time between hormone and growth inhibitor. As a corollary, it would be interesting to investigate the possibility that the reciprocal movements of hormogonia on agar media constitute a response to gradient concentrations of these substances around the margins of colonies.

In view of the fact that auxins tend to be destroyed in the light, it seems unlikely that the beneficial influence of *Caulobacter* is due solely to the contribution of a growth hormone, although this, undoubtedly, is of some importance Other observations support this contention. In particular, the alga is invariably seen to be dark in colour, sometimes almost black, in the presence of *Caulobacter*, whereas pure cultures are commonly a pale green The dark coloration is caused by phycoerythrin which appears to exercise a protective function by absorbing those wave-lengths to which the hormone is susceptible Recently, Boney and Corner[15] have presented evidence to show that this pigment also has a protective function in certain red algae The mechanism by which the bacterium stimulates phycoerythrin production by the alga is not known Apparently light of short wave-lengths is also necessary, however, because the pigment is not produced under red light even with *Caulobacter* present

In this matter, a further observation appears to be especially significant It has been noted already that considerable enlargement of the trichome immediately precedes formation of hormogone It seems not unreasonable to assume that such development might well be favourable to the conservation or build-up of hormone by the alga If the beneficial influence of *Caulobacter* lay only in the provision of hormone, it would be expected that, in cultures containing the bacterium, trichome enlargement would be obviated to some extent In fact, this is found to be true, although the effect is observed to operate only in the early phases in the growth of colonies from single hormogonia Therefore, it must be concluded that direct stimulation is relatively short-lived and must be supplemented or replaced at some stage by hormone production by the alga with the protection afforded by abundant phycoerythrin

A remarkable feature of the early growth of colonies containing *Caulobacter* is that fresh hormogonia are produced not only after minimal trichome development but also without the formation of heterocysts The heterocysts appear to be associated with full trichome enlargement Furthermore, it has been observed that hormogonia originating from fully developed trichomes always emerge from the interior of these bodies, never from the periphery One is immediately reminded of a suggestion by Fritsch[16] that these 'enigmatic' structures might well be concerned with the production of substances controlling growth, cell division, and other developmental processes of blue-green algae It is believed that the present work provides concrete evidence in support of this hypothesis and could also explain the reason why difficulty is sometimes experienced in securing the growth of algae in pure culture J S BUNT

Isolation of Bacteria-free Cultures from Hormogone-producing Blue-Green Algae

THE difficulties associated with obtaining bacteria-free cultures of blue-green algae are well known Various techniques, involving the use of toxic physical or chemical agents combined with patient and careful sub-culture, have been tested in attempts to eliminate contaminants. Of the many agents examined, few have proved to be successful. Allison and Morris[1], Allison *et al.*[2], Bortels,[3] Gerloff *et al.*[4], Fogg[5] and Venkataraman *et al.*[6] have prepared bacteria-free cultures by exposing algal material to ultra-violet light. Fogg[7] purified one species with the aid of chlorine water. De[8] depended on the selectivity of mineral media solidified with silica gel and on extensive sub-culturing to obtain pure cultures. Unfortunately, these techniques have not been found generally applicable[7,8], partly because a large degree of reliance must be placed on chance for success.

In these Laboratories, none of the techniques described in the literature proved satisfactory. A number of others, based on the assumption that an agent might be found to which the algae alone would be insusceptible, gave equally disappointing results. The possibility of using antibiotics has been examined[9], again without success.

In view of these results, it was felt that some technique aimed at the selection of newly formed and uncontaminated trichomes as suggested by Pringsheim[10] rather than the destruction of micro-organisms closely bound in the sheaths of older material might be more rewarding. Such an approach has, of course, already been used where final isolation has been from newly migrated hormogonia. However, the procedures used have seriously limited the chances of success. The method to be described was designed to minimize the operation of chance.

A small amount of inoculum containing a single species of alga is transferred to the surface of a suitable medium solidified with agar previously prepared as a deep, one-third filling a 6 in. × 1 in. culture tube. The material is incubated under appropriate lighting until fresh growth is just visible to the naked eye. Sufficient medium is then added carefully to form a plugging layer 3–5 mm. deep over the developing colony. As soon as this plug has set, 5–10 ml. of the same medium, but without agar, is added and the tube returned to the light room. With the algae under investigation, it was found possible and worth while to incorporate 60 μgm./ml. aureomycin in the plugging medium as an aid to final isolation. After some time, 5–11 days in my experience, young hormogonia and usually small numbers of motile bacteria are found to be present in the supernatant liquid medium although not visible to the naked eye. At this time, a series of small aliquots is transferred to Petri dishes and poured with the chosen medium. In these Laboratories, 10–20 0.1-ml. aliquots are used. The number of plates and the size of the aliquots are chosen to favour the development of isolated uncontaminated colonies. These are located as early as possible by regular microscopic inspection of the plates and immediately transferred to fresh medium. A fine hypodermic needle mounted in a suitable holder and a dissecting microscope have been found indispensable for this purpose. The purity of cultures is checked by normal cultural procedures and by direct microscopic inspection.

Up to the present, six bacteria-free cultures have been obtained, including the genera *Nostoc*, *Anabaena* and *Gloeotrichia*. It is of interest to note that the cultures of *Gloeotrichia* are being maintained on nitrogen-deficient media. Kjeldahl analyses suggest a capacity for nitrogen fixation.

Unfortunately, the technique described has not been found applicable to species which do not form hormogonia readily. However, recent investigations indicate that exposure of such organisms to suitable concentrations of indole-3-acetic acid at light intensities of about 12 ft.-candles may be generally useful for inducing formation of hormogone. In fact, using this technique recently, two further bacteria-free cultures have been obtained of algae that otherwise could not be induced to form hormogonia.

This and the preceding work have been supported by a University of Sydney research grant. Thanks are due to Miss R. Webb for technical assistance.

Use of Antibiotics to purify Blue-Green Algae

THE use of antibiotics in media for tissue cultures suggests that such techniques may also be useful for freeing blue-green algae of contaminants. Our results with antibiotics have not been entirely successful, but it may serve some useful purpose to report them here to avoid possible waste of time by other investigators.

The following substances are inhibitory to algal growth: cetrimide (*n*-cetyl-trimethyl ammonium bromide), dithionyl, streptomycin, neomycin, bacitracin. Actidione, penicillin, chloramphenicol, tetracycline, sulphafurazole, erythromycin, nystatin, novobiocin, oleandomycin, polymyxin, furodantoin and fungostatin are not inhibitory. It is possible to eliminate fungal contaminants by cultivation of algae in the presence of actidione and fungostatin, but not possible to free the algae from bacteria by using singly any of the substances mentioned here.

The following combinations have been used without success: (i) tetracycline–chlorotetracycline, (ii) penicillin–erythromycin–aureomycin, (iii) polymyxin–penicillin–erythromycin–tetracycline. No success was obtained when the algal cultures were pre-treated with 0.002 per cent dithionyl.

It should be reported here that the bacterial contaminants are sensitive to antibiotics when tested in the absence of algae but cannot be eliminated when the algae are present. The algae seem to protect the bacteria against the antibiotics in some way. Also, some of the contaminants would not grow in ordinary meat infusion broth. Therefore, the absence of bacterial growth in broth should not be regarded as a sole criterion for purity of algal cultures.

Vortex Shedding from the End of a Tube as a Result of Buoyancy Effects

ONE of the most interesting phenomena observed in fluid flow is that of vortex shedding, the best known example of which is the von Kármán vortex street behind a cylinder or similar obstacles normal to the flowing stream. For such two-dimensional systems, there is considerable information available. However, for axially symmetric systems, there appears to be little more than the recent results of Magarvey and Bishop[1] on spheres. Therefore, a study of vortex shedding in axially symmetric systems was initiated under Battelle sponsorship. In one system, vortices as shown in Fig. 1 were observed in alkaline water (containing amounts of sodium carbonate neutralized by up to 1·24 c.c. nitric acid/litre) discharging from a long vertical tube into a large plenum chamber. The chamber contained slightly acidic water (up to 7·65 c.c. nitric acid/litre). Reynolds numbers down to the experimental limit of above 200 were investigated. The flow pattern was revealed by phenolphthalein added to the inlet water supply.

The Strouhal number, $\nu D/V$, which characterizes in a dimensionless manner the vortex shedding frequency, varied from about 0·3 to 1·4 in the experiments. The Strouhal number was observed to increase with increasing acidity, with increasing alkalinity, and with decreasing Froude number. Reynolds number did not appear to be an important variable. It would appear that the buoyancy effects produced by the small release of heat at the reaction interface causes the vortex shedding in an otherwise stable flow. This supposition is supported by the observation of similar vortex shedding when a charged platinum ring at the tube exit was used to generate hydrogen bubbles, and when the density of the inflow was reduced slightly by use of a small addition of alcohol.

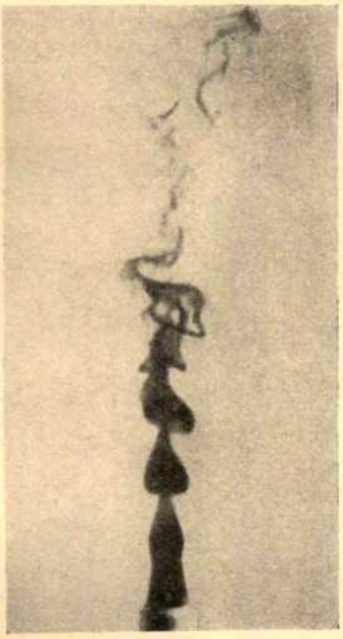

Fig. 1. Vortex formation at discharge of ½ in. diameter tube

One other observation should be reported. Tritton[2] observed, in an investigation of vortex shedding from rods, that at certain combinations of the independent parameters two alternative frequencies rather than one frequency could occur. Sato[3], in work on the instability of two-dimensional jets, made a similar observation. In my system, quite dissimilar to the previous two, we also observed that there were certain combinations of independent variables which led to two alternative frequencies, and, consequently, two alternative Strouhal numbers. In fact, the shifting from one frequency to the other, which often occurred in these instances, led to difficulties in obtaining accurate counts of frequency of vortex formation.

Distribution of Pressure for Flow of Gas through Porous Media

THE permeability coefficient K for flow of gas through a porous medium is defined by the equation[1]:

$$G = -K\frac{\partial c}{\partial x} \qquad (1)$$

where G is the flowing flux in moles through unit cross-sectional area of the medium in unit time, and $\frac{\partial c}{\partial x}$ is the concentration gradient. When the concentration of the gas is expressed in terms of the pressure p, equation (1) becomes:

$$G = -\frac{K}{RT}\frac{\partial p}{\partial x} \qquad (2)$$

If K is a linear function of pressure:

$$K = a + bp \qquad (3)$$

where a and b are constants, equation (2) may be integrated using the boundary conditions: $p = p_i$ (inlet pressure) at $x = L$; $p = p_0$ (outlet pressure) at $x = 0$; $p = f(x)$ $0 < x < L$ for all time.

The solution is:

$$p^2 + \frac{2a}{b}p - \left(\frac{a}{b} + p_m\right)2\Delta p\frac{x}{L} - p_0^2 - \frac{2a}{b}p_0 = 0 \qquad (4)$$

where $\Delta p = p_i - p_0$ = pressure difference, $p_m = (p_i + p_0)/2$ = mean pressure, and L is the length of the medium. This is the general equation for a parabola.

We have measured the pressure at three points inside a split specimen for steady-state flow of nitrogen, carbon dioxide and freon-12 (CF_2Cl_2) through Acheson '*A*' and Morgan '*EY*9' graphites. The experimental pressure distributions approximate to

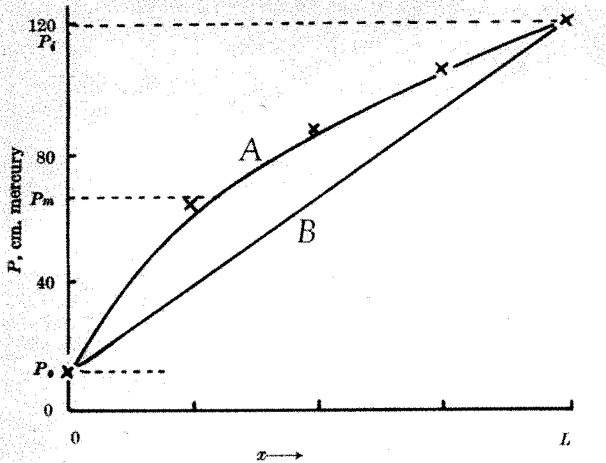

Fig. 1. Distribution of pressure through Acheson '*A*' graphite specimen. Flow gas, nitrogen. p_i = 120·6 cm. mercury, p_0 = 12·1 cm. mercury, L = 3·9 cm.; ×, experimental pressure. Full lines: *A*, parabola calculated from equation (4); *B*, chord

those predicted by equation (4) for $35 < \Delta p < 160$ cm. mercury and $20 < p_m < 120$ cm. mercury. A typical distribution is reproduced in Fig. 1. In practice, the experimental pressures diverge from the theoretical parabola by up to 12 per cent at the centre of the specimen, the experimental error being less than 3 per cent. This divergence may be attributed to three possible causes: (1) inhomogeneity in the graphite (the variation in K through specimens of the two graphites was 30 per cent and 55 per cent respectively); (2) non-linearity of the dependence on pressure of K (in one of the graphites $K = 0{\cdot}25 + 0{\cdot}065\,p - 7 \times 10^{-4}\,p^{1{\cdot}68}$), and (3) possible surface flow of adsorbed gas.

Carman[1] gives the integration of equation (2) as:

$$G = \frac{K}{RT} \cdot \frac{\Delta p}{L} \qquad (5)$$

which he states is valid when Δp is small or K is independent of pressure. Now it may be readily shown from equation (4) that the tangent to the theoretical parabola at $p = p_m$ is parallel to the chord from p_i to p_0, that is, at $p = p_m$, $\frac{\partial p}{\partial x} = \frac{\Delta p}{L}$. This means that (5) may be applied to calculate K at the mean pressure in a porous medium for any Δp provided that K is a linear function of pressure.

Biram[2], in a recent communication, has proposed that the constants a and b in equation (3) can be obtained by measuring the pressure at the mid-point and at both ends of a specimen. The equation he gives may be derived from equation (4). In practice, we find that his method may involve an error as high as 120 per cent due to the reasons mentioned earlier which cause deviations of the experimental pressures from the theoretical parabola.

We also take this opportunity to mention that we have observed minima in the variation of K with pressure for several gases in different graphites at low pressures.

We are indebted to Mr. A. McNab of the New Zealand Department of Scientific and Industrial Research for a helpful discussion. We acknowledge the support of the Australian Atomic Energy Commission in the award of a scholarship to one of us (G. J. F.), and the provision of graphite samples.

The Reaction Silicon-29(*n*,α)Magnesium-26 at 14 MeV. Neutron Energy

A 400 Ω-cm. *n*-type silicon surface barrier detector was irradiated by neutrons of energy 14·03 ± 0·05 MeV. The experimental arrangement is identical with that described in an earlier communication[1] reporting results for (*n*,α) and (*n*,*p*) reactions in silicon-28 at the same neutron energy.

The reaction silicon-29(*n*,α)magnesium-26 has a *Q*-value of − 0·022 MeV., so that although its abundance in natural silicon is only 4·7 per cent it is possible to observe the reaction in competition with the more intense silicon-28 reactions, as the typical energy spectrum of Fig. 1 shows.

The results of Hinds and Middleton[2] for the energy-levels of magnesium-26 enable assignment of the two highest energy groups to the magnesium-26 ground-state and the excited state at 1·801 MeV. The ground-state and first four excited states of magnesium-25, populated by the silicon-28(*n*,α)magnesium-25 reaction, are also present and are labelled.

Dearnaley and Ferguson have examined the reaction silicon-29(*n*,α)magnesium-26 in the nuetron energy-range 5–8 MeV., and report a group which could correspond to transitions to a new first excited state in magnesium-26, located at 1·33 MeV. (ref. 3). Re-examination of the high-energy portion of our previously reported spectra did not yield evidence

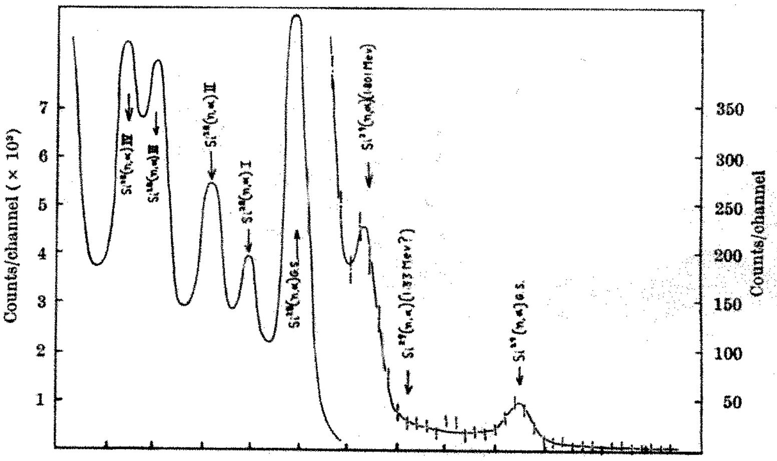

Fig. 1. Spectrum showing the reaction silicon-29(*n*,α)magnesium-26

for such a transition. Re-investigation of the relevant region with improved statistics was undertaken with the results given above, and fails to provide evidence for an alpha-particle group corresponding to the level postulated by Dearnaley and Ferguson.

The approximate cross-section ratio for the magnesium-26 ground-state and 1·801-MeV excited state groups, obtained in the present experiment, agrees with that obtained by Dearnaley and Ferguson at 7·6-MeV. neutron energy. In the absence of a selection rule inhibiting the transition, one would expect the 14 MeV (n,α) spectrum to exhibit a cross-section to the new magnesium-26 level similar to the ground-state cross-section. Fig. 1 indicates that this is not so, and if the level exists the cross-section for the transition to it is less than 0·1 mb.

Previous investigations of the energy-levels of magnesium-26, notably those of Hinds and Middleton, using the reactions magnesium-25(d,p)magnesium-26, aluminium-27(t,α)magnesium-26 and magnesium-24(t,p)magnesium-26, gave no indication of a level in magnesium-26 at 1·33 MeV, nor did the experiment of Glover and Weigold[4], investigating the reaction aluminium-27(n,d)magnesium-26.

Dearnaley and Ferguson have considered and investigated possible sources of contamination and we can offer no obvious explanation for the peak observed in their results. Additional experimental evidence is required to resolve the problem of whether or not the postulated level exists.

GEOCHEMISTRY

Origin of High Tritium Content of Atmospheric Methane, Hydrogen and Stratospheric Water

RECENT work (ref. 1 and Suess, H. E., private communication) has shown that atmospheric methane has a fractional tritium content orders of magnitude higher than that of rain water and approaching that of atmospheric hydrogen and stratospheric water. The rate of increase with time of this tritium in methane makes it appear likely that it originates in the testing of nuclear devices. (The finding by Bishop *et al.*[1] that the specific activity of atmospheric methane appears to be lower in the troposphere than in the stratosphere or at the surface is, however, not obviously explained on the basis of origin in thermonuclear explosion, or for that matter by origin from any single source.) However, no satisfactory mechanism by which such tritium can be incorporated in methane has been advanced. The high temperature and oxidizing conditions supposed to exist in the bomb fireball seemed to rule it out as a source of tritiated methane[1]. Biological processes yielding methane of high specific activity are difficult to conceive; and indeed, sewage methane has little tritium content[1]. High atmosphere, radiation-induced mechanisms for exchange of methane with high specific activity atmospheric hydrogen can be formulated, but these mechanisms suggest that the methane is likely to be oxidized under the conditions required (Libby, W. F., private communication).

The thesis of this communication is that tritiated methane may after all be produced in the fireball, in a reducing atmosphere which I believe must exist at its centre. Thermonuclear weapons are presumably constructed primarily of reducing substances. Following detonation, the hot gas formed from bomb material will push back the surrounding atmosphere to form a reducing core within the fireball. On cooling to about 3,000° C this core will contract to a diameter approaching 100 metres, assuming some reasonable mass of the original weapon. During this stage the fireball is isothermal[2], and it is very unlikely that the large reducing core will mix with its oxidizing surroundings. On further cooling its contents will form molecular species. The tritium may be expected to combine largely as metal hydrides, molecular hydrogen, water, ammonia and hydrocarbons including methane. (The necessary carbon may be derived from conventional explosives and any other carbonaceous material contained in the device.)

At the end of the glowing, isothermal stage the reducing core, now hotter than its surroundings, will presumably tend to rise. During this convection, air will be entrained and the cooling, shrinking bubble of reducing gas may be expected to break up and mix. Insufficient data are openly available to speculate about how much combustion will occur during this process, but it would be surprising if such oxidation were complete.

If the high tritium content of atmospheric methane is due to this mechanism the question arises why this same methane does not also have a high carbon-14 activity[1]. It must be first pointed out that most of the carbon-14 from the $^{14}N(n,p)^{14}C$ reaction will be produced outside the reducing core and will therefore appear as $^{14}CO_2$. However, even if the amount of carbon-14 within the core were of the same magnitude as that of tritium, then atmospheric methane resulting from such events having an activity of 2×10^4 tritium units ($T\ H = 1·5 \times 10^{13}$) would have incremental carbon-14 activity amounting to only about 10 per cent of that of contemporary biosphere carbon.

The hypothesis of a reducing core in a nuclear explosion fireball also suggests that the high tritium content of atmospheric hydrogen[3] of the thermonuclear era arises directly, and is not dependent on, an exchange between molecular hydrogen and tritiated water. Most of the tritium in the fireball will probably be combined in molecular forms other than methane and hydrogen, particularly in metal hydrides. These, and hydrocarbons less stable than methane (for example, acetylene), will afterwards be completely oxidized in the atmosphere to yield water vapour of high specific activity found in the stratosphere[4].

The validity of the suggestion advanced here may be checked in several ways. The most direct involves sampling the fireball gases soon after they have cooled. Later tests on atmospheric gases may be based on the abnormally high ratio of deuterium to protium which may be presumed to exist in the fireball core

Thus there should be an unnaturally high probability that a molecule of atmospheric methane containing tritium contains a deuterium atom as well Such a measurement of the ratio CH_3T CH_2DT will require mass separation prior to the application of low-level counting techniques The ratio of HT DT in atmospheric hydrogen is much easier to determine since these isomers can be separated by gas chromatography[5] The answer here will depend not only on the origin of the tritiated hydrogen, but also on whether it can undergo exchange with atmospheric water

I am indebted to Prof W F Libby and to Dr E A Martell for stimulating discussions of the present proposal This work was supported by the U S Air Force and Atomic Energy Commission

Formation of Pegmatitic Carbonatite in a Syenite–Marble Contact

Immediately north of the village of Karacayir, vilayet Sivas, Turkey, a small intrusion of rather coarse-grained syenite occurs in a banded marble formation of unknown age Here I had occasion to study in some detail a peculiar coarse-grained marble of pegmatitic appearance, containing biotite and apatite The banded marbles seem to be regionally metamorphosed, on which the thermal metamorphism caused by the intrusion is superimposed The part of the marble which protrudes into the syenite is changed into a carbonatite–pegmatite Otherwise the marbles retain their regular banding, which even seems to be accentuated when nearing the contact Within the aureole of thermal metamorphism small crystals of phlogopite and diopside develop in small amounts on the stratification planes as well as throughout the marble Near the contact small dikes of syenite–aplite and more-or-less crushed syenite–pegmatite cut through the marbles, the syenite itself contains locally muscovite

A non-metamorphic fossiliferous impure nummulitic limestone lies unconformably on top of both marble formation and syenite, thereby defining the age of the latter as pre-Eocene Intra-formational conglomerates are polymixt, containing quartz-pebbles, quartzites, quartzitic schists and acid intrusives

Next to calcite the pegmatitic carbonatite contains large (up to 1 in and more) biotite crystals, slender hexagonal prisms of green apatite, and locally small idiomorphic thorianite (ThO_2) crystals In one place a mass of large idiomorphic allanite crystals has been found, of platey habit, up to 1 in across Direct evidence that this carbonatite actually passed through a molten state is not available, as no carbonate-glass was found Wyllie and Tuttle[1] state that "Some carbonate liquids can be quenched to a glass by extremely rapid cooling, but in nature such rapid cooling is unlikely and evidence of melting in rocks will be difficult to find"

The total obliteration of the pre-intrusive structure of the marble, the idiomorphic and coarse-grained habit of its constituent minerals, its obvious permeation with magmatic fluids (addition of thorium, rare earths, phosphorus pentoxide, (Fe,Mg)O silica and water) indicate a pseudo-liquid condition of this carbonatite mass at the time of the syenite intrusion This condition is most probably caused by the presence of a liquid phase, a carbonate melt

According to the same authors[1] the partial melting of carbonates in the presence of water vapour starts at temperatures as low as 650° C , and at pressures reached at relatively high levels in Earth's crust This temperature is almost certainly exceeded during the intrusion of a syenitic magma In another publication Wyllie and Tuttle[2] state that· "Although calcite is generally the dominant mineral in carbonatites apatite and mica are constant accessories" The presence of radioactive and rare-earth minerals (thorianite and allanite) in the carbonatite mass shows its close affinity to 'normal' intrusive carbonatites It is believed, in the light of the results obtained by Wyllie and Tuttle[1,2], that pressure-temperature conditions in this contact provoked the (partial) liquefaction of the marble, which recrystallized on cooling as a pegmatitic mass of carbonatite composition The importance of this example lies in the fact that here a carbonatite, associated as usual with alkaline intrusives, is still indisputably recognizable as the direct continuation of a sedimentary marble Though I certainly do not claim definitely that carbonatites must be formed this way, it shows at least that they may

METALLURGY

Embrittlement of Grain Boundaries by Equilibrium Segregation

Equilibrium segregation of impurities or solute elements has frequently been suggested as a cause of grain boundary embrittlement in metals and metallic compounds, but the evidence has been largely indirect Even if the existence of grain boundary segregation be granted in specific instances, the manner in which such segregation might give rise to embrittlement has remained wholely speculative It is the purpose of this communication to report that in a large number of cases where boundary segregation is established, suspected, or possible, a significant hardening of the grain boundary region relative to that of the interior of the grain is observed by microhardness measurements

A typical result is shown in Fig 1 for a high-purity iron sample treated by Ainslie *et al* [1] in a sulphur-bearing atmosphere and demonstrated by them with tracer techniques to contain sulphur absorbed in grain boundary regions This case appears to be the most firmly established instance of equilibrium grain boundary segregation on record Tests on a com-

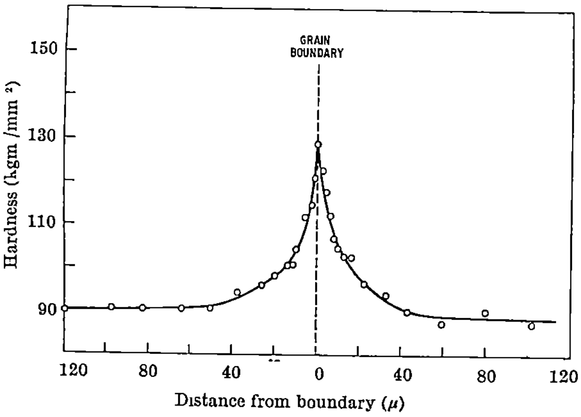

Fig 1

panion sample which had been subjected by Ainslie *et al* to identical heat treatment in sulphur-free atmosphere showed no boundary hardening whatsoever The intensity of the peak hardening in the sulphur-segregated iron (about 40 per cent), and the extent of the measurable effect (about 50μ either side of the boundary) are typical, but hardness differences of as much as 60 per cent and breadths as great as 100μ on each side have been observed in some cases with other systems Although effects of relative orientation of grains undoubtedly exist, they appear to be small since comparable hardening is observed in all boundaries of a randomly oriented polycrystalline sample

Table 1 lists some of the cases in which grain boundary hardening by equilibrium segregation has been observed in the present investigation Later publications will report these results in more detail

Table 1

Base material	Suspected segregant	Typical $\frac{\Delta H}{H}$ %	References suggesting segregation or reporting embrittlement by trace amounts of impurity
Iron	S	43	Ainslie *et al* (ref 1)
Iron	O	30	Low and Feustel (ref 2)
Aluminium bronze	Al	13	Perryman (ref 3)
Beryllides	O and/or N	50	Lewis (ref 4)
Silicides	O and/or N	33	Fitzer (ref 5)
Miscellaneous intermetallics, for example, AgMg, NiAl, Ni_3Al, CoCr-σ, Ni_3Ti, etc	frequently O and/or N	15–60	Westbrook and Wood (unpublished work)

Our experiments show certain features which appear to be common to the general phenomenology of the effect

Among these are

(1) Segregation is dependent on temperature In some instances, segregation, and therefore grain boundary hardening, disappears at high temperatures It is therefore possible, in favourable circumstances to eliminate segregation and improve toughness by quenching

(2) Segregation is frequently modified by the presence of another trace impurity, for example, segregation of oxygen does not occur in iron bearing small amounts of carbon but only in decarburized iron

(3) Grain boundary hardening by segregation in intermetallic compounds seems only to occur when there is a stoichiometric excess of a chemically active element

(4) Kinetics of segregation and desegregation are extremely rapid, suggesting lateral transport of segregant along some 'short circuiting' diffusion path

Previous suggestions for mechanisms of grain boundary embrittlement by segregation have involved internal stresses, changes in melting point, and changes in surface energy While all are conceptually plausible, no such mechanism has had unambiguous experimental support It is now clear that in a large number of cases embrittlement results from the creation of a barrier to dislocation propagation by formation of a hardened region at and near the boundary Whether this hardening occurs by a solution hardening mechanism or by changes in the dislocation density and structure at and near boundaries is not yet certain and the particular source of hardening may well vary from one case to another In the particular case of iron-sulphur, the extensive networks of dislocations adjacent to grain boundaries revealed in the transmission electron micrographs of Ainslie *et al* [6] are adequate to account for the observed boundary hardening

We are grateful to Messrs N G Ainslie, E A Aitken and J R Low for the loan of samples, to A J Peat for assistance, and to J R Low, A U. Seybolt and D Turnbull for helpful discussion

Stress Concentration Effects in Tertiary Creep

In most cases, fracture under high-temperature creep conditions results from the formation and linking up of small voids on the grain boundaries within the metal A period of accelerating creep precedes the fracture and it is generally assumed that this acceleration is caused by the reduction in stress-carrying area through the formation of these voids[1,2]

It has recently been shown that the density of a material during creep decreases at an approximately linear rate up to the onset of tertiary creep but thereafter decreases at a continuously increasing rate until fracture ensues[3] If stress concentration is the cause of tertiary creep, the reduction in cross-section must have increased the stress to a value which gives a detectable change in the rate of deformation at this stage Clearly the dependence on stress of the rate of creep will then be an important factor in determining when this increase in creep-rate will be detectable and also in the rate of acceleration to fracture, that is in the fraction of the total time to rupture which is spent in tertiary creep

Some recent work[4] on nickel alloys containing only 0 012 wt per cent of tin is significant in this respect When tested at 400° C this material is extremely dependent on stress, a stress increase of 10 per cent giving an increase in minimum creep-rate and a decrease in fracture-life by a factor of 10^3 On the basis of a stress concentration mechanism for tertiary creep it might therefore be expected that a very rapid acceleration to fracture would be observed at an early stage of creep However, this is found not to be the case. The shape of the creep curves for this material is very similar to those for pure nickel at this temperature and similar to tests on the same material at higher temperatures where no large stress-dependent effects are observed

Considerable necking occurred before fracture at 400° C, but this must have occurred at a late stage of tertiary creep since only a small amount of necking would have been sufficient to give almost immediate fracture with a material having such a stress-dependent creep-rate

We conclude, therefore, that stress concentration, effected by void formation or necking, is not important in causing the acceleration in creep-rate before fracture

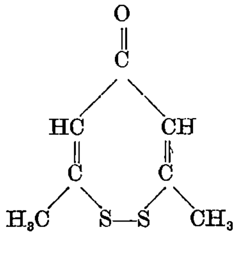
CHEMISTRY

Crystal Structure of 2,5-Dimethyl-Dithio-Furophthene, a Homologue of Thio-Thiophthene

DURING work on a series of sulphurated cyclic compounds[1], we have determined the structure of a substance to which formula I was previously ascribed



(I)

The substance crystallizes from toluene as yellow-orange prisms, often twinned, belonging to a monoclinic system, space-group $P2_1/c$, four molecules are in the unit cell of dimensions·

$$a = 4·44 \quad b = 10·78 \quad c = 17·20 \text{ Å}. \quad \beta = 97° 20'$$

Observed density 1·40 gm cm $^{-3}$· calculated 1·42

Single-crystal precession and Weissenberg photographs enabled us to carry out X-ray analysis on both (100) and (010) projections We determined the structure not with a heavy-atom method but using Sayre's direct method[2] The usual refinement process, based on a few Fourier and difference syntheses, gave the present values for the reliability index, $R = 0·21$ and $R = 0·13$ for $0kl$ and $h0l$ reflexions, respectively

Within experimental error, the molecule is planar, maximum perpendicular distance from mean plane being 0·04 Å. Fig 1 shows the molecular shape with bond lengths and angles, the corresponding shape of thio-thiophthene, as obtained after the last refinement, being also drawn for comparison (broken line)

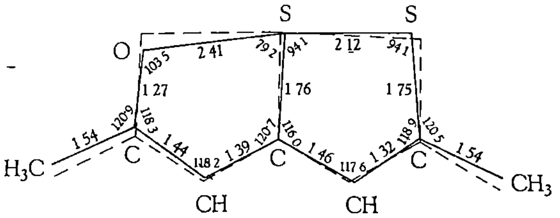


Fig 1

The oxygen–sulphur–sulphur system is seen to be almost linear, with the oxygen atom in the extreme position These results are in full agreement with the structure proposed in ref 3, and confirmed in ref 4 with the aid of nuclear magnetic resonance analysis Further chemical evidence was recently provided in ref 5

A comparison of this structure with the thio-thiophthene system is of great interest. The two molecules have about the same shape, structural configuration and crystal packing substitution of one sulphur atom with oxygen only causes the electronic arrangement to be slightly different In fact, we know that each sulphur–sulphur bond in thio-thiophthene may be regarded as made up from both fractional σ and π bonds, the bond orders being 0·707 and 0·439, respectively[6] The σ and π exchange integrals are, approximately, β and $\frac{1}{2}\beta$ (where β is the carbon–carbon π exchange integral), so that the bond is longer than the single one, even with a bond order sum greater than unity

Substitution of one sulphur atom by oxygen allows the same electronic interaction to take place only to a much less extent, owing to the different electronegativities of sulphur and oxygen, and to the much smaller overlap between the orbitals of the two atoms The sulphur–oxygen σ and π overlap integrals for a distance of 2·41 Å are, in fact, reduced to approximately one-third the values for the sulphur–sulphur interaction in the thio-thiophthene This reduction must also result in a corresponding increase of sulphur–sulphur overlap integral, in the oxygen–sulphur–sulphur system.

This discussion gives a satisfactory account of the following experimental data shortening of the sulphur–sulphur bond (2·12 Å) with respect to thio-thiophthene (the σ bond order is very close to unity), carbon–oxygen distance only slightly longer (1·27 Å) than the double-bond distance, rather distinct localization of double bonds in the carbon atoms chain, central carbon–sulphur bond length nearly the same as the other

From Fig 1 we can also notice in the present structure a reduction of valence angles not only in the right ring, but also in the left one This means that the abnormal sulphur oxygen length (2·41 Å), half-way between a single bond and Van der Waals distance, is chiefly to be considered a consequence of the reluctance toward distortion of the carbon atom valence angles From a geometrical point of view, it may be noted that the carbonylic group is anyway held in the molecular plane by its resonance with the dienic system We can say, therefore, that the essential features characterizing thio-thiophthene are present in this structure, but to a small extent, so that the actual electronic distribution is best represented by the formula shown in Fig 2, in which are also indicated, for each bond, the percentage of

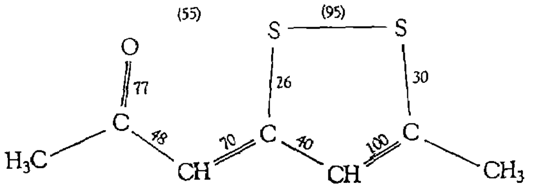

Fig. 2

double bond (or of single bond relatively to Van der Waals radii, for oxygen–sulphur and sulphur–sulphur distances)

For these reasons, the denominations suggested by Prof Richter, Beilstein Institute, Hamburg (cf ref 5), must be accepted as very rational and exact; for 2,5-dimethyl-thio-thiophthene it is:

meribicyclo-epidithio-(2,4)-eptadien-thion(6)

and for 2,5-dimethyl-dithio-furophthene it is:

epidithio-(2,4)-eptadien-on(6)

Further theoretical investigations, of the type performed by Giacometti and Rigatti[6] for thio-thiophthene, are under way, and will give a more exact description Some other compounds, homologous with thio-thiophthene, with sulphur atoms substituted by possible other group VI elements, are now under examination.

We gladly acknowledge the financial support by Shell International Research Maatschappij N.V , The Hague, Netherlands.

Hydrogen Bonding in Alkyl Phosphonic and Alkyl Phosphonothionic Acids

In a recent series of papers[1], Peppard *et al* have examined alkyl and aryl phosphoric and phosphonic acids and their esters As a result of cryoscopic and infra-red measurements, they have concluded that, except in acetic acid solution, organophosphorus acids are dimeric, or polymeric, depending on the solvent, and that there is no evidence of the monomer in dilute solutions (*M*/1,000) in carbon tetrachloride They conclude that the hydrogen bonding in these acids is stronger than that in carboxylic acids These conclusions are in agreement with those reached by earlier workers[2-5], who all report the bonding to be unaffected by dilution in non-polar solvents In view of these findings, it has been suggested[3,6] that the hydrogen bonding may be intramolecular

Examination of more dilute solutions of ethyl methylphosphonic and ethyl methylphosphonothionic acids has shown that, if the dilution is great enough, these hydrogen bonds can be broken, and that the bonding is therefore inter- and not intra-molecular

Using carefully dried carbon tetrachloride as the solvent, path-lengths of up to 10 cm and double-beam compensation of solvent absorption, the results shown in Figs 1 and 2 were obtained With ethyl methylphosphonothionic acid (Fig 1), the initial bonded —OH absorption band at 3 27μ (3,058 cm^{-1}) decreases in intensity, relative to the C—H absorption band at 3 4μ (2,940 cm^{-1}), as the concentration of the solution decreases, and is replaced by a new absorption band at 2 78μ (3,600 cm^{-1}). In addition, a band at 4 35μ (2,300 cm^{-1}) progressively decreases in intensity and is replaced by a band at 4 65μ (2,150 cm^{-1})

In the case of ethyl methylphosphonic acid, the evidence is not so complete owing to experimental limitations No indication of breaking of hydrogen bonds is obtained in solutions more concentrated than *M*/3,000 Comparing the spectrum of a 1-cm path-length of this concentration with that of a 10-cm path-length of *M*/30,000 (Fig 2) shows that the absorption band at 3 8μ (2,630 cm^{-1}) has decreased in intensity relative to the C—H absorption at 3 4μ (2,940 cm^{-1}) and that a new band is appearing at 3 1μ (3,230 cm^{-1}) It was not possible to investigate this problem further as the spectrophotometer would neither accommodate a longer absorption cell nor produce reliable spectra from more dilute solutions over the same absorption path. It might be possible, however, to continue the observations using means such as electronic scale expansion The detection of a change in the intensity of the bonded OH absorption band, together with the appearance of a band at higher frequency, shows that the hydrogen

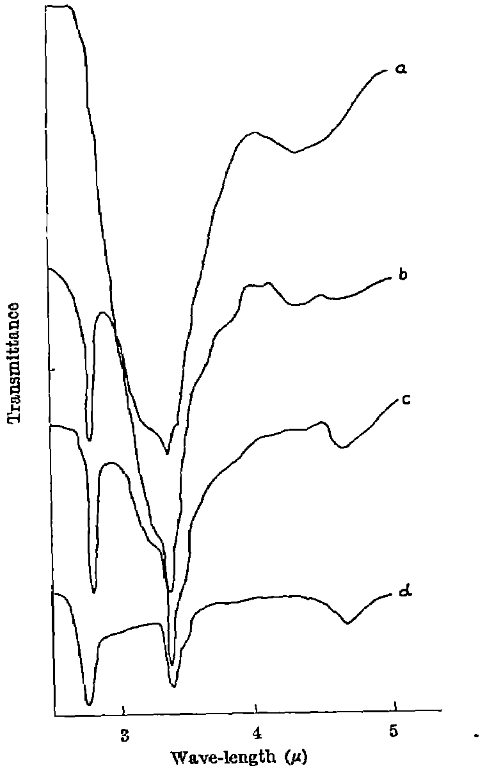

Fig 1 Spectra of ethyl methylphosphonothionic acid (*a*) Capillary film, undiluted (*b*) *M*/350 in carbon tetrachloride, 1 cm , (*c*) *M*/1,750 in carbon tetrachloride, 5 cm , (*d*) *M*/3,500 in carbon tetrachloride, 5 cm

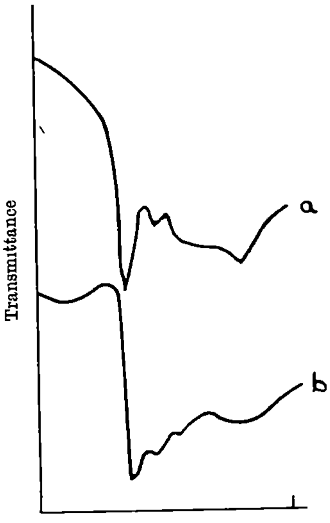

Fig. 2. Spectra of ethyl methylphosphonic acid in dilute solution. (a) *M*/3,000 solution in carbon tetrachloride, 1 cm.; (b) *M*/30,000 solution in carbon tetrachloride, 10 cm.

bonds are beginning to break in very dilute solution. It is therefore concluded that, as in the case of the phosphonothionic acid, the hydrogen bonds must be inter- rather than intra-molecular.

These experiments also throw some light on the assignment of the absorption bands associated with the $\mathrm{P(\!=\!S)OH}$ and $\mathrm{P(\!=\!O)OH}$ groupings. The $\mathrm{P{-}OH}$ group in $\mathrm{{>}P(\!=\!S)OH}$ compounds is characterized by absorption bands in the regions (*a*) 3,000–3,100 cm.$^{-1}$ and (*b*) 2,200–2,360 cm.$^{-1}$, whereas the same group in $\mathrm{{>}P(\!=\!O)OH}$ compounds has four characteristic bands in the regions (*a*) 2,525–2,725 cm.$^{-1}$, (*b*) 2,150–2,350 cm.$^{-1}$, (*c*) 1,600–1,700 cm.$^{-1}$, (*d*) 480–530 cm.$^{-1}$.

As bands (*a*) and (*b*) occur in both types, these must be vibrations associated solely with the P—O—H vibrations, band (*a*) being the O—H valency vibration. In view of the movement of band (*b*) to lower frequencies when the hydrogen bonds are broken, this band is assigned to a combination band involving the OH deformation vibration. Observations on deuteration, which will be reported in more detail elsewhere, have indicated that the O—H deformation vibration in P—O—H groups is in the vicinity of 1,250 cm.$^{-1}$. This is contrary to the assignments for this band given by Bellamy[2] and Corbridge[7], but in agreement with those of Ryskin and Stavitskaya[8]. The P—O—(H) vibration is found in the range 910–1,030 cm.$^{-1}$ (ref. 6) and the combination of the P—O—(H) vibration with the O—H deformation vibration would then result in a frequency in the range ascribed to band (*b*), which is therefore assigned to a combination of these vibrations.

Band (*c*) in $\mathrm{{>}P(\!=\!O)OH}$ compounds has been assigned[3,6] to the O—H deformation vibration. In the light of evidence from deuteration this assignment is no longer valid. As this band does not appear in $\mathrm{{>}P(\!=\!S)OH}$ compounds, it may be a combination band involving the P=O vibration. As this occurs in the region of 1,200 cm.$^{-1}$, this implies a frequency in the region 400–500 cm.$^{-1}$ for the other component. Band (*c*) is therefore tentatively assigned to a combination of the P=O valency vibration and of band (*d*), which is otherwise unassigned.

Synthesis of the Toxic Principle of *Dichapetalum toxicarium* (18-Fluoro-*cis*-9-Octadecenoic Acid)

Dichapetalum toxicarium (*Chailletia toxicaria*, Don) a shrub occurring in Sierra Leone, produces a hard and woody fruit which is extremely toxic to warm-blooded animals. The pharmacological, medical, and historical aspects of this plant have recently been reviewed[1]. Peters and colleagues have concluded[2], on the basis of nuclear magnetic resonance, infra-red spectroscopy and ozonolysis, that the toxic principle is 18-fluoro-*cis*-9-octadecenoic acid (ω-fluoro-oleic acid), $F(CH_2)_8CH{=}CH(CH_2)_7COOH$. It was in order to confirm this conclusion that the following synthesis of ω-fluoro-oleic acid was undertaken.

$$F(CH_2)_8Br + NaC{\equiv}CH \rightarrow F(CH_2)_8C{\equiv}CH + I(CH_2)_7Cl \rightarrow$$
$$F(CH_2)_8C{\equiv}C(CH_2)_7Cl + NaCN \rightarrow F(CH_2)_8C{\equiv}C(CH_2)_7CN \rightarrow$$
$$F(CH_2)_8\,C{\equiv}C(CH_2)_7CONH_2 \rightarrow F(CH_2)_8C{\equiv}C(CH_2)_7COOH \rightarrow$$
$$F(CH_2)_8CH{=}CH(CH_2)_7COOH\ (cis)$$

Using *N*,*N*-dimethylformamide and xylene as solvents, 8-fluoro-octyl bromide[3] was converted to 10-fluoro-1-decyne in 60 per cent yield, b.p. 81–82° (10 mm.), n_D^{25} 1.4250, d_4^{20} 0.877 (found: C, 76.48; H, 11.02. $C_{10}H_{17}F$ requires C, 76.87; H, 10.97 per cent). Previous work[4] had indicated that the ω-fluoro-1-alkynes, in the presence of reactants such as sodamide and Grignard reagents, tended to lose fluorine rather than form the expected acetylenic organometallic derivative; however, by using metallic lithium in liquid ammonia, 10-fluoro-1-decyne formed 1-chloro-17-fluoro-8-heptadecyne in 89 per cent yield, b.p. 137° (0.25 mm.), n_D^{25} 1.4610, d_4^{20} 0.969 (found: C, 70.56; H, 10.38; Cl, 12.42. $C_{17}H_{30}ClF$ requires C, 70.68; H, 10.47; Cl, 12.28 per cent). Reaction of this last compound with sodium cyanide in dimethyl sulphoxide gave the corresponding nitrile in 93.5 per cent yield, b.p. 139° (0.025 mm.), n_D^{25} 1.4578 (found: C, 77.29; H, 10.77; N, 4.79

$C_{18}H_{30}FN$ requires C, 77 36, H, 10 82, N, 5 01 per cent)

Preliminary work using 15-cyano-1-fluoro-7-pentadecyne had indicated the difficulty of hydrolysing this type of nitrile, because the triple bond is susceptible to acidic reagents and the fluorine to vigorous alkaline treatment The required ω-fluorostearolic acid was ultimately obtained in 73 per cent yield by treatment of 1-cyano-17-fluoro-8-heptadecyne with hydrogen peroxide and alkali followed by hydrolysis of the resultant amide with alcoholic potassium hydroxide, m p 52–53° from aqueous methanol (found C, 72 50, H, 10 28 $C_{18}H_{31}FO_2$ requires C, 72 31, H, 10 47 per cent) Stereospecific partial hydrogenation of this fluoroacetylenic acid using Lindlar catalyst gave a 99 per cent yield of ω-fluoro-oleic acid, recrystallized from 30–60° petroleum ether at 2° (found C, 71 92, H, 11 21, F, 6 16 $C_{18}H_{33}FO_2$ requires C, 71 95, H, 11 07, F, 6 32 per cent) The overall yield from 8-fluoro-octyl bromide was 36 per cent The physical properties of this acid are shown in Table 1 and are compared with those of a sample of the naturally occurring acid provided by Peters Hydrogenation of the synthetic ω-fluoro-oleic acid using platinum and hydrogen formed ω-fluorostearic acid, m p 77–78° from methanol, mixed with authentic ω-fluorostearic acid[5], m p 76–77°

‡ c /s from tetramethylsilane

§ Spin–spin interaction with adjacent methylene group

The proton resonance spectral data are listed in Table 1 The ω-CH_2 group appeared as a doublet of triplets centred at 258 c /s for the natural material and at 259 c /s for the synthetic acid, the splitting is due to spin–spin interaction with the terminal fluorine and the adjacent methylene group The coupling constants were the same in each case The olefinic protons absorbed at 317 c /s and 316 c /s for the two samples, again with identical coupling constants, the olefinic protons in a sample of oleic acid also gave exactly the same results (ν = 316 c /s , J = 5 c /s) The results determined for the natural product are in good agreement with those previously reported[2]

There can thus be little doubt that the toxic principle of *Dichapetalum toxicarium* is indeed ω-fluoro-oleic acid This acid is only the second known naturally occurring organic fluorine compound, the first being fluoroacetic acid It is not improbable that there is some biogenetic relationship between the two compounds Further work on this and other ω-fluoro unsaturated acids is in progress

We thank Sir Rudolph Peters for kindly providing us with a sample of the naturally occurring acid, Allied Chemical Corporation, General Chemical Division, Morristown, N J , for financial assistance, and Dr J B Stothers of this Department for help with the nuclear magnetic resonance spectra

Effect of Strong Electrical Fields on the Boiling Points of some Alcohols

Katti and Chaudhri[1] have published a set of measurements on the effect of electrical fields on the boiling points of methanol, ethanol, and isopropanol This is an effect which can be calculated from the first principles of thermodynamics

A boiling liquid in an electrical field does both electrical and pressure-volume work, the conservation of energy equation is $dU = TdS - PdV + EdP'$, where P is the pressure, P' the polarization and E the electric field Hence the chemical potential of the liquid may be written as

$$d\mu_1 = -s_1 dT + v_1 dP - p_{1'} dE$$

where small italics stand for gram molecular quantities The condition of phase equilibrium is $d\mu_1 = d\mu_g$, hence $(dT/dE)_P = -\Delta p_{1'\to g}/\Delta s_{1\to g}$. The equation is exactly analogous to the Claperon equation

For such liquids as methanol, $p' = (\varepsilon - 1)vE$, so that

$$\frac{dT}{T} = \frac{(\varepsilon_1 - 1)v_1 - (\varepsilon_g - 1)v_g}{\Delta h} E dE$$

If the electrical work stored in the liquid is small compared with the heat of vaporization at zero field, and the change in boiling points is so small that one can ignore changes in the dielectric constants of liquid and vapour, then this equation may be integrated Approximating $\ln T/T_0$ as $\Delta T/T_0$, we find that

$$\Delta T = T_0 \frac{(\varepsilon_1 - 1)v_1 - (\varepsilon_g - 1)v_g}{2\Delta h} E^2$$

This equation is valid for a system in which all the material, liquid and vapour, remains within the field If experiments are done in a constant-volume container (as were Katti and Chaudhri's), a term must be added to the conservation of energy equation to account for the work done in removing vapour from the field This has the effect of changing v_g to v_1 Since $\varepsilon_g - 1$ is very small compared to $\varepsilon_1 - 1$, this correction is not important, even though the molar volume of the gas is much greater than that of the liquid

It should be noted that Katti and Chaudhri used an a c field They did not give the frequency, but it was presumably low enough for the dielectric constants to be approximately equal to their d c values and high enough for their Beckmann thermometer to respond to the average temperature In this case one can calculate the expected change in temperature, taking E as its root mean square value.

Since $\Delta T = C E^2$, where C is a combination of the molecular constants, and using standard values[2] one finds that C in M K S units equals 5 3, 5 5 and 5 7 × 10^{-17} for methanol, ethanol, and isopropanol respectively. Hence, for example, methanol at 5 kV /cm will show a rise of boiling point of 1 3 × 10^{-5} deg C At 5 kV /cm Katti and Chaudhri observed boiling point depressions of 2 0, 0·7, and 0 4 deg. C for methanol, ethanol, and isopropanol, respectively, in complete disagreement with theory

I thank Dr E R Nightingale for helpful discussions, and Esso Research and Engineering for permission to publish this communication

[1] Katti, P K , and Chaudhri, M M , *Nature*, 190, 80 (1961)

[2] Lange, N A , *Handbook of Chemistry* (Handbook Publishers, Inc , Sandusky, 1949), *International Critical Tables* (McGraw-Hill, New York, 1926)

Since the publication of our communication in *Nature*, several attempts have been made to explain this phenomenon and to calculate the magnitude of the lowering of the boiling points These attempts naturally deal with the application of thermodynamics to the mechanical effects arising out of the application of strong electrical fields to dielectrics These models, however, predict very small lowering of the boiling points (of the order of 10^{-5} deg. C. for fields of the order of 5 kV /cm)

In fact we ourselves were led to this investigation nearly two years ago because of a suggestion by Prof D S Kothari based on the Clapeyron equation with change of pressure replaced by $KE^2/8\pi$ We did not refer to this in our communication because a reference to it was made in an earlier book on physical chemistry and secondly because the sign and the magnitude of the observed changes in the boiling points are not in agreement with this model

The main purpose of our communication was to point out the unusually large depression of the boiling points of the liquids under the experimental conditions used More experimental work is clearly necessary, and we hope to report on further results in due course

The Optical F Absorption Band

In a recent communication[1] a new model for the optical F absorption band was proposed for the alkali metal azides From a study of irradiation-produced bands in the visible and infra-red region of the absorption spectrum of the azides, it was shown that the anion (N_3^-) was intimately related to the F absorption band and it was suggested that the F band was caused by a 'charge-transfer' complex of the type discussed extensively in the chemical literature, especially by Mulliken[2] The 'charge-transfer' complex consists of a dative bond being established between one electron donor and an electron acceptor with a concomitant electronic absorption belonging to the complex as a whole

Table 1. ENERGY DIFFERENCE BETWEEN FIRST ULTRA-VIOLET PEAK AND THE F BAND*

	$h\nu_1 - h\nu_F = C$		$h\nu_1 - h\nu_F = C$
LiF	12 4 −5 0 = 7 4	LiBr	7 2 −2 7 = 4 5
NaF	10 6 −3 6 = 7 0	NaBr	6 78−2 3 = 4 48
KF	9 95−2 7 = 7 25	KBr	6 77−2 0 = 4 77
LiCl	8 8 −3 1 = 5 7	RbBr	6 6 −1 8 = 4 8
NaCl	7 95−2 7 = 5 25	KI	5 8 −1 8 = 4 0
KCl	7 76−2 2 = 5 56	RbI	5 7 −1 6 = 4 1
RbCl	7 5 −2 0 = 5 5		

* $h\nu_1$, energy of first ultra-violet band from Eby, J E , Teegarden, K J , and Dutton, D B , *Phys Rev* ,116, 1099 (1959), $h\nu_F$ energy of the F band from Dekker, A J , *Solid State Physics* (Prentice Hall, 1959), $h\nu_1$, for LiF estimated from H C Kremers, *Indust and Eng Chem* , 32, 1478 (1940)

For the azides, the following mechanism was proposed for the formation of the 'charge-transfer' complex and the resulting absorption band Under ultra-violet irradiation an interstitial metal atom is ionized, this metal ion now moves to a position of lower potential energy, that is, to a cation vacancy and as a consequence the equilibrium crystal field is so perturbed (in an unspecified manner) as to set up a 'charge-transfer' complex between that cation and a neighbouring anion. Thus in the proposed model the F absorption band depends on the existence of cation vacancies rather than anion vacancies

I feel that the phenomena in the halides cannot be essentially different from those in the azides If one accepts the importance of cation vacancies then several phenomena in the halides can be understood in a straightforward manner. For example, the following experimental facts strongly suggest the importance of the cation vacancy The electrical conductivity of crystals is decreased by darkening[3] Plastic strain which enhances conductivity enhances darkening by X-ray irradiation[3] Divalent cation impurities which increase ionic conductivity enhance colorability by irradiation[3].

The role of the anion in the F band in the halides is not easily demonstrated as in the azides, since there is no infra-red vibration associated with it except for the lattice vibration However, I suggest that the correlation between the F band and the first ultra-violet absorption band in the halides, first pointed out by Glasner and Tompkins[4], be interpreted in a manner similar to that in the azides Table 1 lists the difference in energy between the first ultra-violet absorption band in uncoloured crystals and the F band produced in the crystals It can be seen that the energy difference is a constant for any particular anion It is generally accepted[5] that the first ultra-violet absorption peak in the halides is caused by the removal of an electron from a halogen ion to a neighbouring metal ion Our suggested model for the F band is the *partial* removal of an electron to a neighbouring metal ion so that it is not surprising that there exists a relationship between the ultra-violet band and the F band Further, a colourless electronegative ion with an absorption band in the ultra-violet, under a perturbing influence (the formation of a bond with increasingly greater covalent character), would expect to have an absorption band increase in wave-length proportional to the degree of perturbation[6] One might expect that any such perturbation would have the greatest effect on the most ionic system If we use Pauling's function[6], $1-\exp(-\frac{1}{4}(X_a-X_b)^2)$ (where X_a and X_b are the electro-negativities of the atoms in the bond), as a measure of the ionic character for the halides, then the fluorides appear to be most ionic and the iodides least so and the difference in energy between the ultra-violet band and the *F* band varies in the expected manner My proposed model for the *F* absorption band is a point defect where just such a phenomenon is occurring

I cannot justify the imposition of a special site for a cation vacancy which afterwards captures a metal ion except to say that perhaps the ion does not completely enter the vacancy or that there is incomplete relaxation about the vacancy caused by other defects in the neighbourhood

It has been shown[7] that normal sodium chloride contains about 10^{17} interstitial sodium atoms/c c and thus the model yields a plausible mechanism for the formation of *F* centres by low-energy irradiation The 'charge-transfer' complex also allows one to understand more easily the dichroism observed in *F* centres[8]

Perhaps the most serious drawback to the model is that no explanation is given for the observed electron spin resonance in coloured crystals I suggest that the electron which is removed from the interstitial metal atom is trapped at another centre giving rise to the electron spin resonance The optical *F* absorption band and electron spin resonance appear simultaneously but come from two different points in the crystal.

BIOCHEMISTRY

Particle Involvement in Fatty Acid Synthesis in Liver and Yeast Systems

THE synthesis of fatty acids from acetate has been shown to occur in particle-free supernatant fractions obtained from a variety of mammalian tissues[1-3] An examination of the literature[4-7] reveals that such synthesis is significantly increased in the presence of a microsomal fraction (While the term microsome may be used to describe the particle fraction prepared from liver, it is premature to refer to yeast particles by this name since the cytological fractionation of the yeast cell is less well established As used here, the term particles refers to the fraction sedimented, after prior removal of the mitochondrial fraction, at 100,000*g* for 45 min 'Supernatant' refers to the solution obtained after removal of the 100,000*g* pellet) We have shown, for example, that the addition of rat liver microsomes, in appropriate amounts, results in an increase in the incorporation of acetate carbon into fatty acids many times greater than that observed with the rat liver supernatant fraction alone[8] Similar observations have been made with a yeast system[9]

Table 1 EFFECTS OF ADDITION OF PARTICLES ON FATTY ACID SYNTHESIS FROM ACETATE IN LIVER AND YEAST SYSTEMS

Supernatant alone	After addition of liver microsomes (ml)				After addition of yeast particles (ml)			
	0 025	0 05	0 10	0 30	0 025	0 05	0 10	0 30
Liver, 13 6	25 1	46 2	32 6	7 6	41 1	33 4	23 0	14 2
Yeast, 10 3	13 5	13 2	7 3	3 8	27 3	34 8	29 4	24 9

40 μmoles of potassium phosphate buffer (*p*H 7 5), 15 μmoles of reduced glutathione (K^+ salt) 18 μmoles of $MgCl_2$, 0 25 μmole of $MnCl_2$, 2 5 μmoles of $KHCO_3$, 1 25 μmoles of potassium acetate-1-^{14}C (3 × 10^5 c p m), 12 μmoles of ATP (K^+ salt), 0 03 μmole of CoA, 0 125 μmole of TPN, and 18 8 μmoles of potassium citrate, all contained in 0 5 ml , were incubated with 0 4 ml of a particle-free supernatant fraction (11 9 mgm protein for liver, 8 8 mgm protein for yeast) plus the amount of particle suspension (in 0 1 *M* phosphate buffer, *p*H 7 5) recorded above (55 mgm per ml protein for liver, 67 mgm. per ml. protein for yeast) for 2 hr at 37° C with air as the gas phase The preparation of the liver and yeast fractions in 0 1 *M* phosphate buffer (*p*H 7 5) has been described (refs 9, 14) The fatty acids were isolated and assayed for carbon-14 activity as described in ref 15 All values above represent mμmoles of acetate converted to fatty acids per mgm supernatant protein

The failure of other workers to observe particle stimulation in mammalian preparations[1,10]—as well as the report that removal of these particles actually increased synthesis[7]—may be explained by our present findings (Table 1), which show that microsomes increase fatty acid synthesis over only a narrow range of concentrations Indeed, additions of excess amounts of particles reduced synthesis below that observed with the supernatant fraction alone Since adenosine triphosphate (ATP) is an absolute requirement for fatty acid synthesis from acetate, our findings of high ATPase activity in liver microsomes offers a reasonable explanation for this inhibitory action of the microsomes The inhibition observed with moderately large amounts of microsomes can be relieved by increasing the ATP concentration in the incubation medium

Table 1 also shows that yeast particles can be substituted for liver microsomes in the experiments with liver supernatant fractions. Here again, fatty acid synthesis from acetate reached its optimum in the presence of specific amounts of yeast particles, but dropped when those amounts were increased The addition of liver microsomes to the yeast supernatant fraction failed to augment fatty acid synthesis, but their inhibitory property at high levels was retained Fatty acid synthesis in the yeast system was less sensitive to large amounts of yeast particles

The addition of particles also increased the incorporation of the carbon-14 of acetyl-1-^{14}C-coenzyme A (CoA) into fatty acids, but did not affect fatty acid synthesis from malonyl-CoA (Table 2) These findings suggest that particles exerted their effect before the formation of malonyl-CoA in both systems Evidence that this may be the case in the yeast system comes from the observation that yeast particles are rela-

Table 2 EFFECT OF PARTICLES ON INCORPORATION OF THE CARBON-14 OF ACETATE-1-^{14}C, ACETYL-1-^{14}C-COA AND MALONYL-2-^{14}C-COA INTO FATTY ACIDS BY RAT LIVER AND YEAST PREPARATIONS

Labelled substrate	Percentage of carbon-14 incorporated into fatty acids			
	Rat liver		Yeast	
	Supernatant alone	Supernatant + microsomes	Supernatant alone	Supernatant + particles
Acetate-1-^{14}C	5 9	32 3	3 7	23 2
Acetyl-1-^{14}C-CoA	6 1	24 6	4 1	17 1
Malonyl-2-^{14}C-CoA	44 0	51 6	38 5	46 2

60 μmoles of glycylglycine-KOH buffer (*p*H 7 5), 15 μmoles reduced glutathione (K^+ salt), 18 μmoles of $MgCl_2$ 0 25 μmole of $MnCl_2$, 2 5 μmoles of $KHCO_3$, 12 μmoles ATP (K^+ salt), 0 125 μmole of TPN, 18 8 μmoles of potassium citrate and either (*a*) 0 12 μmole of potassium acetate-1-^{14}C (4 5 × 10^5 c p m) plus 0 12 μmole of CoA or (*b*) 0 12 μmole of acetyl-1-^{14}C-CoA (9 4 × 10^4 c p m) or (*c*) 0 12 μmole of malonyl-2-^{14}C-CoA (2 3 × 10^5 c p m) plus 0 02 μmole of acetyl-CoA, all contained in 0 5 ml , were incubated with 0 4 ml of particle-free supernatant fraction (7 8 mgm protein for liver and yeast) and 0 1 ml of particle suspension (2 1 mgm protein for liver and 5 4 mgm protein for yeast), as described in Table 1

Table 3 Incorporation of the Carbon-14 of Acetate-1-^{14}C, Acetyl-1-^{14}C-CoA and Malonyl-2-^{14}C-CoA into Fatty Acids by Rat Liver and Yeast Particles incubated Alone

Labelled substrate	Percentage of carbon-14 incorporated into fatty acids	
	Liver microsomes	Yeast particles
Acetate-1-^{14}C	0 2	20 3
Acetyl-1-^{14}C-CoA	0 3	14 7
Malonyl-2-^{14}C-CoA	29 0	15 8

60 μmoles of glycylglycine-KOH buffer (pH 7 5), 15 μmoles of reduced glutathione (K^+ salt), 18 μmoles of $MgCl_2$, 0 25 μmole of $MnCl_2$, 2 5 μmoles of $KHCO_3$, 12 μmoles of ATP (K^+ salt), 1 μmole of TPNH, and either (*a*) 0 12 μmole of potassium acetate-1-^{14}C (4 5 × 10^5 c p m) plus 0 12 μmole of CoA or (*b*) 0 12 μmole of acetyl-1-^{14}C-CoA (9 4 × 10^4 c p m) or (*c*) 0 12 μmole of malonyl-2-^{14}C-CoA (2 3 × 10^5 c p m) plus 0 02 μmole of acetyl-CoA, all contained in 0 5 ml , were incubated with 0 1 ml of particle suspension (2 1 mgm protein for liver and 5 4 mgm protein for yeast), as described in Table 1

tively rich in acetyl-CoA carboxylase activity[11] However, the results reported here indicate that this explanation is not tenable for the liver system

Particles from liver and yeast were incubated with acetate, acetyl-CoA, or malonyl-CoA, under the conditions shown in Table 3 Liver particles, by themselves, incorporated into fatty acids appreciable amounts of the carbon-14 of malonyl-2-^{14}C-CoA, but not of acetate-1-^{14}C or acetyl-1-^{14}C-CoA Under identical conditions, yeast particles converted significant amounts of all three substrates to fatty acids That yeast particles have an enzyme system capable of the complete conversion of acetate to fatty acids receives support from our observation that they contain acetokinase activity equivalent, on a protein basis, to that found in the supernatant fraction (Klein, H P , and Den, H , unpublished observations) Liver particles, on the other hand, presumably lack acetyl-CoA carboxylase activity, and may be devoid of acetokinase activity With malonyl-CoA as substrate, if no added co-factor is rate limiting, an additive effect would be expected when the two fractions of each system are combined But this was not observed (Table 2) The relation of this fatty acid-synthesizing system in the particles to fatty acid synthesis in the system composed of the supernatant fraction plus particles remains to be elucidated

Although the increase in fatty acid synthesis from acetate and from acetyl-CoA induced by liver microsomes is not due to their ability to convert acetyl-CoA and bicarbonate to malonyl-CoA, the possibility exists that malonyl-CoA is supplied through an interaction between the particles and the supernatant fraction It is conceivable that some compound in the system may donate a carboxyl group to acetyl-CoA without passing through a bicarbonate pool (cf Swick and Wood[12]) We have reported[8] that, while glucose-6-phosphate or malate will produce adequate amounts of reduced triphosphopyridine nucleotide (TPNH) for fatty acid synthesis from acetate in mammalian systems, these compounds do not stimulate fatty acid synthesis as effectively as do citrate, isocitrate, and aconitate These tricarboxylic acids, which yield amounts of TPNH comparable with those formed from malate or glucose-6-phosphate, are distinctly superior in their capacity to augment fatty acid synthesis from acetate or acetyl-CoA (The addition of liver microsomes to the supernatant fraction oxidizing citrate-6-^{14}C will increase the rate and level of $^{14}CO_2$ production) It is therefore reasonable to infer that the tertiary carboxyl group of citrate may be involved in a transcarboxylation reaction with acetyl-CoA leading to the formation of malonyl-CoA The supernatant fraction, containing isocitric dehydrogenase and aconitase, would initiate this reaction, which would then be completed by particles through a transcarboxylase reaction Numa *et al* [13] were unable to demonstrate transcarboxylase activity in rat liver preparations, but their examination of transcarboxylase activity was confined to the particle-free supernatant fraction only

Comparative Effects of 2,4-Dinitrophenol on the Actomyosin Adenosine Triphosphatase from Fresh, Frozen and Freeze-dried Beef

In our work on biochemical alterations in beef consequent upon freeze-drying the evidence obtained so far indicates that the changes are probably subtle Previously[1] we reported that there is little change between the salt solubility of frozen and freeze-dried beef and that only small differences occurred in the amount of sedimentable actomyosin No consistent difference appeared in the adenosine triphosphatase (ATPase) activity of actomyosin extracts from these materials, and the electrophoretic patterns shown by sarcoplasmic protein extracts were almost identical for frozen and freeze-dried beef, under the conditions used With contractile protein extracts there was noticeable alteration in the freeze-dried pattern indicating denaturation

In present work reported here, designed to detect ageing changes in beef, I have compared the stimulatory effects of 2,4-dinitrophenol (DNP) on actomyosin ATPase preparations from fresh, frozen and freeze-dried beef While there were no demonstrable changes ascribable to ageing, I observed a consistently greater stimulation by DNP of the actomyosin ATPase from fresh beef than from frozen and freeze-dried beef

Actomyosin extracts were prepared in two ways from semitendinosus and longissimus dorsi muscles. Precipitated actomyosin was prepared by the conventional technique of extraction with 0.53 ionic strength buffer pH 8.2 and dilution to ionic strength 0.08. Actomyosin obtained indirectly was prepared as previously described[1]. The only procedural change was the substitution of a Virtis blender (1½ min.) for the Waring blender.

Beef carcasses (hindquarters or short hips right and left sides) were received on the dates shown in Table 1. Muscle designated as 'not aged' was excised within 18 hr. of receipt. From this, samples labelled 'fresh' were taken for immediate analysis. The remainder was frozen in air at −29° C for periods of 24–48 hr. The frozen muscle was cut into slices 3/4 in. thick. One portion was kept frozen and the other freeze-dried by radiant heating at a chamber pressure between 0.4 and 0.5 mm. mercury[2]. Analyses of the frozen samples were begun during this 48-hr. period. Freeze-dried samples were vacuum-packed immediately on removal from the drying chamber, and stored at −29° C. Analyses of the latter were always made within 2 weeks of freeze-drying.

Samples designated as 'aged' were taken from the opposite hind limb, which was hung (aged) for 3 weeks at +4° C. At the end of the ageing period the muscles were excised and treated in the same manner as the unaged samples.

The ATPase activities of the extracts were determined at 30° C in a manner similar to that described previously[1], the final concentration of reactants being calcium chloride 0.005 *M*, DNP 0.004 *M*, ATP 0.0025 *M*, potassium chloride 0.10 *M*, *tris*-(hydroxymethylaminomethane) 0.05 *M*, pH 8.1. The concentration of enzyme giving a linear reaction-rate for the 10-min. period was found to be between 0.200 and 0.300 mgm. nitrogen.

The results are shown in Table 1.

S.T., Semitendinosus muscle; L/D, longissimus dorsi muscle; F.D., freeze-dried.

It is well known that DNP stimulates the calcium-activated ATPase of myosin and actomyosin[3-5]. However, no previous report appears to be available concerning the effect of DNP on actomyosin from post-rigor muscle. The mechanism by which stimulation is achieved is not agreed upon. At temperatures above 16° C, DNP also stimulates the cytidine triphosphatase (CTPase) activity of myosin but inhibits the inosine and guanosine triphosphatase (ITPase, GTPase) activity[6,7]. It has been postulated that retardation of hydrolysis of the former two enzymes results from the interaction of —SH or other groups in the enzyme and the 6-NH_2 group common to both adenine and cytosine. This retardation is relieved or removed by the action of DNP on the rate-retarding group of the protein[6-8]. There is no such retardation with the 6-OH base present, for example inosine, and DNP does not stimulate hydrolysis.

Gilmour and Griffiths[5] have suggested that since myosin aggregates at 25° C, there is consequent masking of the active centres. At 0° C there is no masking and no stimulation by DNP. At the higher temperature, DNP is thought to achieve its effect by splitting the polymer and restoring the enzyme to the state in which it exists at 0° C.

The finding of Perry and Chappell[4] that stimulation of myosin ATPase is depressed by an increasing actin/myosin ratio in synthetically prepared actomyosins also bears on the interpretation of these results. The mechanism by which actin can reverse the DNP effect is not understood, but it is presumed that actin can alter the nature or sequence of events at the active centres of myosin.

In the light of the foregoing, the results presented in Table 1 may be interpreted in either of two ways. The depressed stimulation shown by the frozen and freeze-dried samples could be due to unmasking of the active centres during freezing and drying. This would imply the existence of some depolymerizing process as a result of freezing or drying. It is highly unlikely that depolymerization occurs[1]. Moreover, the DNP–ATPase activities of the pellet from actomyosin fractionated at high speed (Cole, unpublished results) show no consistent differences from those of the supernatant liquid. If particle-size affected the DNP–ATPase this would be reflected in greater stimulation of pellet enzyme material.

A second and more logical interpretation of the results reported above can be based on a changed or changing active myosin/actin ratio. A preferential denaturation of myosin in the actomyosin complex would decrease this ratio and thus decrease the stimulatory effect of DNP.

I wish to thank Dr. W. R. Smithies for having the samples of freeze-dried meat prepared and to acknowledge the technical assistance of Mrs. Helen Kent.

Formation of Auxin-bound Proteins

THE occurrence of auxin–protein complexes has been recognized for a long time, but very little is known about the mechanism of the binding process According to Siegel and Galston[1] energy for the coupling of auxin to protein is supplied by adenosine triphosphate, and the process can be inhibited by several metabolic inhibitors Galston *et al* [2,3] have observed, using indole-3-acetic acid (IAA) labelled with carbon-14, that auxin is not bound appreciably to any of the cell organelles but that the particle-free supernatant contains macro-molecules to which auxin is bound. Masuda[4] has recently put forward the suggestion that IAA may render ribonucleic acid (RNA) separate from ribonucleoprotein by becoming complexed with the protein moiety. During the course of an investigation on the binding of auxin to protein in growing tissues it was observed that several amino-acids stimulated the binding process This communication summarizes some of the observations made concerning the inter-relationship between the binding process and protein synthesis

The auxin used was naphthalene acetic acid-1-^{14}C (NAA-^{14}C) obtained from Tracerlab Inc , Waltham, Mass , United States The specific activity of this preparation was rather low (6 7 μc./mgm) , in the experiments described here, concentrations lower than 5×10^{-4} *M* could not be used To study the effect of amino-acids on the binding of NAA-^{14}C to protein, pea-internode sections (var Duke of Albany) were allowed to metabolize different amino-acids in phosphate buffer of *p*H 6 0 in the presence of NAA-^{14}C, and the proteins precipitated by trichloracetic acid (TCA) It can be seen from Table 1 that all the amino-acids used promoted the binding of NAA-^{14}C to protein, and the stimulation was particularly noteworthy in the case of aspartic acid With aspartic acid, glutamic acid and leucine, incorporation of carbon-14 into the TCA-precipitable proteins was higher at 10^{-3} *M* than at 10^{-6} *M* It is not known, however, whether these amino-acids or the auxin-amino-acid conjugates—if such conjugates were formed in the present case—participated in the formation of the auxin-bound protein

Table 1 EFFECT OF AMINO-ACIDS ON THE BINDING OF NAA-^{14}C TO THE 'PROTEIN' of PEA (VAR DUKE OF ALBANY) INTERNODES

If new protein is formed, it may be expected that chloramphenicol—which has been reported to be an inhibitor of protein synthesis—would inhibit the process of formation of the auxin-bound protein Accordingly, internode sections were incubated with three different concentrations of chloramphenicol The results are shown in Fig 1 It is surprising to note that even at 10^{-3} *M* no inhibition was observed, 10^{-5} *M* chloramphenicol brought about a stimulation Some inhibition was observed if the NAA-^{14}C was added 1 hr after pre-incubation with chloramphenicol.

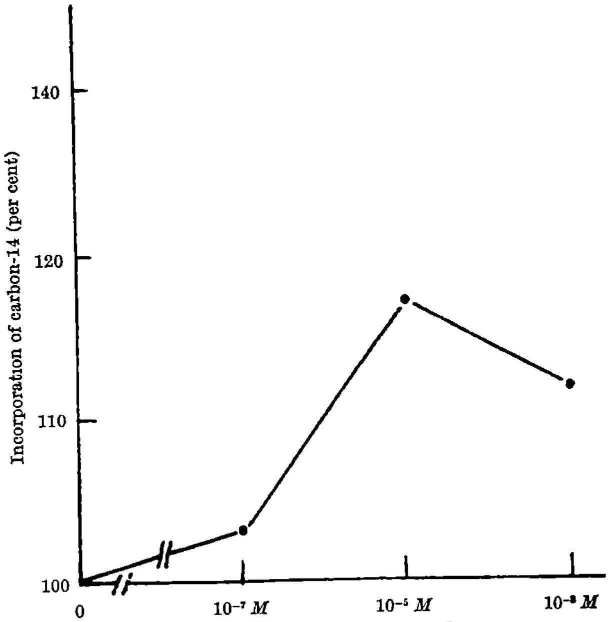

Fig 1 Effect of chloramphenicol on the binding of NAA-^{14}C to protein of internodes of peas

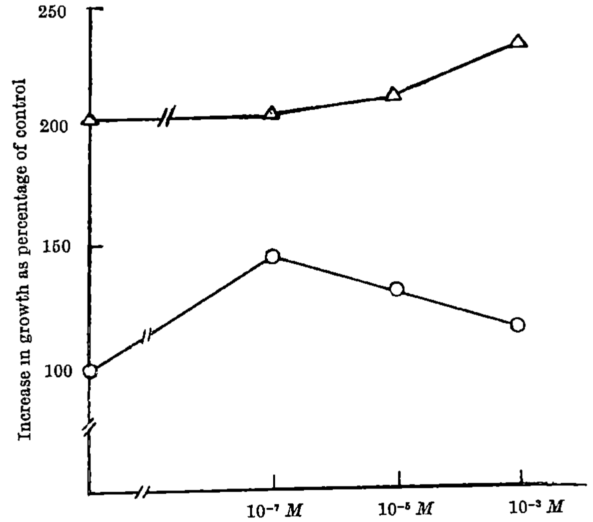

Fig 2 The effect of different concentrations of chloramphenicol on the growth of *Avena* coleoptiles in presence (△) or absence (○) of 10^{-6} *M* IAA

Since the binding of auxin to protein is usually supposed to be related to the growth process, it was necessary to see whether chloramphenicol inhibited auxin-induced growth. The results are shown in Fig. 2 Chloramphenicol not only fails to inhibit growth, but also has no marked effect on the incorporation of ^{14}C-labelled amino-acids into the proteins At 10^{-3} *M* some inhibition was observed in the case of glycine-2-^{14}C (Table 2)

In subsequent experiments the effect of ribonuclease (bovine pancreas RNase, Sigma Chemical Co , St Louis, Mo , U S A.) on the binding process was investigated *Avena* coleoptiles were used, since from the work of Masuda[5] it appears that RNase penetrates coleoptile sections The coleoptiles were treated with RNase (100 μgm /ml) for 2 5 hr ,

Table 2 EFFECT OF CONCENTRATIONS OF CHLORAMPHENICOL ON THE INCORPORATION OF GLYCINE-2-^{14}C AND LEUCINE-1-^{14}C INTO THE 'PROTEIN' OF PEA (VAR DUKE OF ALBANY) INTERNODES

	10^{-3} *M*	84
Leucine-1-^{14}C ($5 \times 10^{-4}M$)	0	100
	10^{-6} *M*	133
	10^{-3} *M*	98

Table 3 EFFECT OF RNASE ON THE BINDING OF NAA-^{14}C TO THE 'PROTEIN' OF PEA (VAR DUKE OF ALBANY) INTERNODES

Treatment	c p m /mgm of 'protein' after 3 hr.
Control	600
RNase (100 μgm /ml)	809

washed and incubated again for 3 hr in darkness at 28° C. in the presence of NAA-^{14}C From Table 3 it is apparent that treatment with RNase has no inhibitory effect On the other hand, some stimulation was observed No inhibition was found even when the period of incubation with NAA-^{14}C was reduced to 1 hr—a period much shorter than that required by the coleoptiles to overcome the inhibitory effect of RNase[4] The process of binding of auxin to protein, thus, does not appear to be an RNA-controlled process. Whether the stimulation in binding due to RNase treatment is caused by the liberation of nucleotides[5] which help in the binding of auxin to protein, or due to an increased availability of sites for the binding of auxin owing to the separation of RNA from ribonucleoprotein, is not known at present

Effect of Indole-3-Acetic Acid (IAA) on Phosphorus Metabolism in the *Avena* Coleoptile

IT is generally believed that energy-rich phosphate compounds act as a store-house of energy for different reactions during growth The auxin-induced stimulation of respiration is presumed to be due to an increased availability of phosphate acceptors due to the rapid utilization of nucleotides during the growth process[1-3] Rhodes and Ashworth[4] have speculated on the mechanism by which growth substances may be metabolized for the generation of energy-rich phosphate bonds, but an unequivocal demonstration of the stimulation of nucleotide synthesis is not available Ormrod and Williams[5] and Key *et al*[6] have recently observed increased phosphorylating activities in plants sprayed with 2,4-dichlorophenoxyacetic acid Marre and Forti[7] had noted a rapid increase in high-energy phosphate level in auxin-treated pea internode segments during the first 30 min, followed by a decline The method of estimation of adenosine triphosphate (ATP) adopted by them, which involves the adsorption of adenine nucleotides on charcoal followed by elution with hydrochloric acid, has several limitations when applied to tissue sections Since numerous metabolic reactions go on in the cell at the same time, and a large number of them concern the participation of nucleotides, particularly reactions mediated by the kinase type of enzyme, and the phosphate residues are transferred to a variety of substrates, estimation of the level of adenine nucleotides at any given time is not the true measure of the total ATP formed during the experimental period A more correct approach is to estimate the phosphate esterified to organic compounds including the nucleotides Phosphate labelled with phosphorus-32 may be conveniently used for this purpose and the present communication summarizes the findings of an investigation directed towards this objective

Five-mm sections of 4-days old *Avena* coleoptiles (var *N P* 1) were incubated with radioactive disodium hydrogen phosphate (Na$_2$H^{32}PO$_4$) and different concentrations of IAA in *M*/150 phosphate buffer of *p*H 6 0 for 1 and 2 hr. The tissues were extracted with 80 per cent ethanol and the concentrated extract chromatographed two-dimensionally with phenol/water as the first, and butanol/acetic acid/water (4 1 1) as the second, solvent for 48 hr., or unidimensionally in 69 per cent butyric acid in 0 85 per cent sodium hydroxide, followed by autoradiography with Ilford X-ray films The sum of the ^{32}P-activities in the radiation spots other than inorganic phosphate was taken as a measure of phosphate-^{32}P esterified. It may be observed from Fig 1 that with low concentrations of IAA in the experimental solution, esterification of ^{32}P was increased considerably, at 10^{-3} *M*, a concentration which was inhibitory to growth, esterification was also inhibited The stimulation in esterification

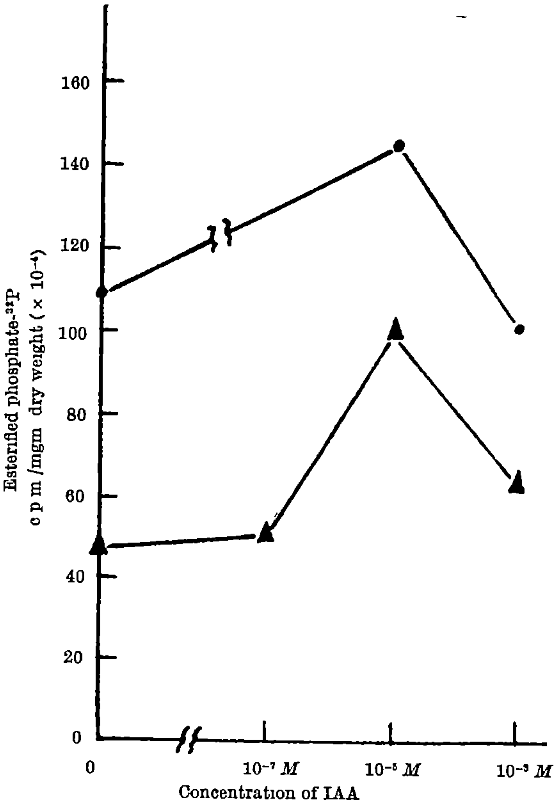

Fig 1 Effect of different concentrations of IAA, in presence (▲) or absence (●) of DNP (10^{-5} *M*) on esterification of phosphorus-32 (from Na$_2$H^{32}PO$_4$) in the 80 per cent ethanol-soluble fraction of *Avena* coleoptile sections, experimental period 2 hr

observed at the end of 1 hr was greater than that after 2 hr Similar results were obtained with rice coleoptiles

When 10^{-5} M 2,4-dinitrophenol (DNP), the uncoupling agent of phosphorylation, was included in the experimental solution it was found that DNP itself inhibited the esterification of phosphate-^{32}P by more than 50 per cent The inhibitory effect was countered by low concentrations of IAA IAA at 10^{-7} M had very little effect, but the higher concentration of 10^{-5} M considerably diminished the inhibitory effect due to DNP IAA at 10^{-3} M, which inhibited esterification, failed to oppose the effect of DNP to any great extent

The effect of IAA and DNP on individual compounds is shown in Table 1 Phosphate-^{32}P was metabolized mainly to hexose phosphates, ATP and ADP, and an unidentified compound designated 'compound X' in Table 1 While changes in activity in the sugar phosphates and adenine nucleotides reflected the pattern observed in investigation of phosphate esterification, incorporation of phosphorus-32 into compound X increased with increasing concentrations of IAA DNP completely inhibited its formation, it reappeared only when DNP was combined with 10^{-3} M IAA

Table 1 Effect of IAA and DNP on the Incorporation of Phosphorus-32 from $Na_2H^{32}PO_4$ into the 80 per cent Ethanol-soluble Phosphorylated Compounds of *Avena* Coleoptiles Specific Activity (c p m /mgm × 10^{-3}) after Inhalation for 2 hr

Treatment	Hexose phosphate	ADP + ATP	'Compound X'
Control	154 6	545 4	75 1
IAA 10^{-5} M	269 6	721 8	162 7
IAA 10^{-3} M	203 9	365 5	164 7
DNP 10^{-5} M	97 1	235 0	0
DNP 10^{-5} M + IAA 10^{-7} M	89 2	185 0	0
DNP 10^{-5} M + IAA 10^{-5} M	152 7	322 2	0
DNP 10^{-5} M + IAA 10^{-3} M	120 8	316 4	26 8

Results obtained in this work reveal an increased incorporation of phosphorus-32 in both the alcohol-insoluble fraction and in the esterified organic compounds in the alcohol-soluble fraction in the presence of low concentrations of IAA which promote the growth of coleoptiles If the phosphorylase and phosphatase activities of these tissues are not very high, this may be taken to reflect largely, if not entirely, the formation of energy-rich nucleotides as affected by auxins The inhibition by DNP and its counter-action by IAA provide further evidence in support of the contention that application of auxins leads to metabolic changes resulting in an increased synthesis of energy-rich nucleotides utilized in various reactions involved in the growth process

Quantitative Aspects of the Re-utilization of Protein-bound Amino-acids *in vivo*

The extent of the re-utilization of protein-bound amino-acids in the formation of new protein has been a subject of interest for many years[1-3] The main difficulty with some of the work reported in the literature has been that the half-life of the protein into which the re-utilized amino-acid residue was traced was short Thus, when one injects a labelled soluble protein and determines the uptake of the label into liver or serum proteins (the half-lives of which are a few days in extent) one deals with a situation in which the uptake, transfer and loss of label is rapid and, furthermore, where the 'recipient' protein continually recirculates some of the amino-acid to itself In these circumstances one is unable to assess reliably the significance or extent of the re-utilization

In this communication we describe the quantitative re-utilization of amino-acids from serum protein to globin Globin is a protein which, contained in the red cell, enjoys a life-span of about 55 days in the rat Thus, over a reasonably short period no globin formed during that interval of time is broken down

22 hr after injecting a rat with 1 mc (about 20 mgm) of glycine-2-^{14}C, the animal was bled and serum albumin and serum globulin were prepared by methods described in ref 3 20 mgm of either labelled serum albumin or serum globulin containing 65 mμc / mgm were injected intravenously into recipient rats Animals were killed 1, 3, 6, 9, 12 or 15 days after the injection and globin was prepared from washed erythrocytes by the method in ref 4 Dry protein powders[3] of the globin and also of aliquots of the injected serum protein were hydrolysed in 6 N hydrochloric acid for 24 hr and the hydrolysate was then treated with 2,4-dinitrofluorobenzene according to Levy[5] The dinitrophenyl glycine was separated from the other dinitrophenyl-amino-acids on a 'Celite' column and purified as described in ref 6 Samples of the injected protein and of the dinitrophenyl glycine from injected protein and from globin were counted using a D-47 Nuclear-Chicago flow-gas counter with 'Mylar' window When sample weights differed from 30 mgm a self-absorption correction was applied In addition, the counts obtained for dinitrophenyl glycine samples were recalculated for free glycine

In preliminary experiments we found that the half-life of serum albumin is 3 days and of serum globulin is 4 days in the Sherman strain rats used in these experiments Furthermore, it was established that about 31 per cent of the radioactivity of serum albumin or serum globulin is due to glycine when these proteins are prepared as described here and the remainder of the activity is in serine In experiments to be reported in full elsewhere it was also found that the conversion of labelled serine to labelled glycine, in recipient animals injected with glycine-serine labelled serum proteins, does not materially affect the results of the calculation presented here

Using the data obtained in the above experiments it is possible to calculate the percentage serum albumin and serum globulin glycine re-utilized in globin synthesis The percentage of the total glycine required for globin synthesis which has its origin in serum protein glycine can also be determined

The calculation is based on the counts/min /mgm of globin glycine found at time t after injection, the total serum protein-bound glycine activity injected into the rat, the assumption that 3 4 per cent of the body-weight corresponds to the total packed red cell volume, that there are 314 mgm of hæmoglobin/ml packed cells[7] and that the life-span of red cells is 55 days in the rat[8] Furthermore, the glycine content of globin is assumed to be 4 8 per cent[9], that of serum globulin 4 3 per cent and that of serum albumin 1 6 per cent[9,10], the molecular weight of hæmoglobin is taken at 68,000 and that of globin at 65,400 (ref 11) The sample calculation presented here is one which is based on a rat injected with labelled rat serum globulin and killed 12 days later

The final calculated results are typical of those obtained in rats injected with serum globulin and killed at any of the times after injection mentioned here

A sample calculation of the re-utilization of serum globulin glycine in globin biosynthesis is as follows

(1) Total glycine radioactivity released on breakdown of injected labelled serum globulin from time 0 to time t (t = 12 days) Counts/min injected × percentage activity in glycine × fraction degraded at time t = 196,500 × 31 per cent × 87 5 per cent = 53,300

(2) Total mgm glycine released a day on breakdown of serum globulins Rat weight (gm) × ml serum/gm body-weight × mgm serum globulin/ml × percentage glycine in serum globulin × fraction of serum globulin degraded a day = 283 × 0 034 × 32 2 × 4 3 per cent × 16 per cent = 2 13

(3) Total mgm glycine required in globin synthesis a day in this rat Weight of rat (gm) × ml packed red cell volume per gm body-weight × mgm hæmoglobin/ml × $\frac{\text{M W globin}}{\text{M W hæmoglobin}}$ × per cent glycine in globin × $\frac{1}{\text{life span of red cells}}$ = 283 × 0 034 × 314 × $\frac{65{,}400}{68{,}000}$ × 4 8 per cent × $\frac{1}{55}$ = 2 54

(4) Total radioactivity incorporated into total globin glycine from time 0 to time t (t = 12 days) Counts/min /mgm globin glycine × total mgm globin glycine = counts/min /mgm globin glycine × mgm glycine required in globin synthesis a day × life-span of globin = 4 38 × 2 54 × 55 = 612

(5) Percentage serum globulin glycine radioactivity incorporated into globin glycine

$$\frac{\text{total counts/min in globin glycine}}{\text{total glycine counts/min released from serum globulin}} \times 100 = \frac{612}{53{,}300} \times 100 = 1\ 15$$

(6) Weight of serum globulin glycine incorporated into globin glycine over this 12-day time-period mgm serum globulin glycine released per day × days × fraction serum globulin glycine counts/min incorporated in globin = 2 13 × 12 × 0 0115 = 0 294

(7) Percentage of total glycine required in globin synthesis which has its origin in serum globulin glycine·

$$\frac{\text{Weight of serum globulin glycine incorporated into globin}}{\text{Total mgm. glycine incorporated into globin in 12 days}} \times 100 = \frac{0\ 294}{2\ 54 \times 12} \times 100 = 0\ 96$$

Thus about 0 96 per cent of the total glycine required in globin synthesis has its origin in serum globulin and approximately 1 15 per cent of serum globulin glycine is used for globin synthesis Similar experiments with rats injected with labelled serum albumin indicate that 0 57 per cent of the total glycine required in globin synthesis has its origin in serum albumin and approximately 1 per cent of serum albumin glycine is used for globin synthesis This contribution by serum proteins of 1 5 per cent of the total glycine required in globin synthesis must be deemed significant in view of the fact that serum proteins constitute only 2 per cent of the rat's total proteins.

Isolation of Echinochrome *A* from the Spines of the Sea Urchin, *Stomopneustes variolaris* (Lamarck)

I have reported the presence of echinochrome *A* (7-ethyl-2,3,5,6,8-pentahydroxy-1,4-naphthaquinone) in the spines of the sea urchin, *Echinarachnius* (Scaphechinus) *mirabilis*[1] and *Diadema setosum*[2]. Recently it was found that the principal naphthaquinone pigment in the almost black spines of the sea urchin, *Stomopneustes variolaris* (Lamarck) (Japanese name, kuro-uni), which was collected at Shirahama in Wakayama Prefecture, was identical with echinochrome *A* The isolation and purification of the pigment have been carried out by the identical method used in the case of *Diadema setosum*

The pure pigment crystallized from dioxane–water in dark red-brown needles and melted at 215° The yield of the pure material was about 26 mgm from each 100 gm of the spines Absorption maxima were at 256, 340, 466, 489, 525 mμ in chloroform and the percentage of carbon and hydrogen was 53 63 and 3 40 respectively (calc for $C_{12}H_{10}O_7$ C, 54 14, H, 3 79)

The trimethyl derivative of the pigment was obtained as long, red needles when it was methylated with diazomethane and crystallized from dioxane–water It melted at 130° (sealed tube) and showed absorption maxima at 249, 323 5, 478, 503, 538 mμ in chloroform The percentage of carbon and hydrogen was 58 53 and 4 96 respectively (calc for $C_{12}H_7O_4$-

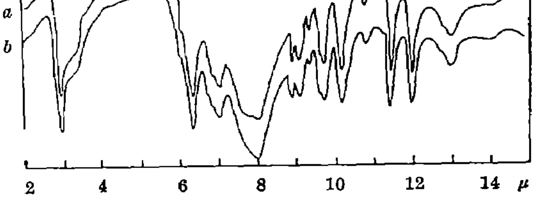

Fig 1 Infra-red spectra *a*, free pigment of *Stomopneustes variolaris*, *b*, echinochrome *A* of *Diadema setosum* (potassium bromide)

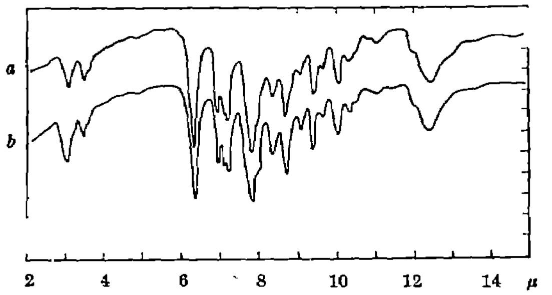

Fig. 2 Infra-red spectra *a*, trimethyl derivative of the pigment of *Stomopneustes variolaris*, *b*, trimethyl echinochrome *A* of *Diadema setosum* (potassium bromide)

$(OCH_3)_3$: C, 58 35, H, 5 29) It was soluble in aqueous sodium hydroxide giving a blue colour

The yellow dehydro-derivative having absorption maxima at 257·5, 319, 392 mμ (in aqueous methanol) was obtained when the free pigment was dehydrogenated with the peroxidase–hydrogen peroxide system. The original red pigment was regenerated when the dehydro derivative was treated with hydrogen sulphide.

The colour reactions and the ultra-violet, visible and infra-red absorption spectra of the free pigment and of the trimethyl derivative were in fair agreement with those of authentic specimens of echinochrome *A* and trimethyl echinochrome *A*, respectively. No depression of the melting point was observed when the mixed melting point examination was carried out with authentic specimens of echinochrome *A* and trimethyl echinochrome *A*, respectively

I wish to thank Prof Y. Nakamura and Prof T. Saito, of Hokkaido University, for their encouragement and guidance I am also grateful to Dr. H Utinomi, of Seto Marine Biological Laboratory, Kyoto University, for collecting samples, and to Dr M Fujino, of Takeda Research Laboratory, for the elemental and infra-red analysis

PHYSIOLOGY

Inhibitory Phenomena and 'Habituation' at the Neuronal Level

In behavioural habituation, according to Thorpe[1], the animal "learns not to respond to stimuli which tend to be without significance in the life of the animal" It does so by a mechanism which determines a "relatively permanent waning of a response as a result of repeated stimulation" Different authors conceive that the phenomenon of habituation may be correlated with changes in the central nervous system (*a*) development of inhibitory connexions, in a way analogous to the extinction of a conditioned reflex[2], (*b*) development of inhibitory influences acting on different synaptic relays of the sensory pathways, which, by producing 'afferent neuronal habituation', would lead to behavioural habituation[3]

We have attempted to analyse the nature of these changes in the snail, in which behavioural habituation was described long ago (Humphrey, 1933, quoted by Thorpe[1]) In electrophysiological investigations with intracellular microelectrodes on the ganglion cells of the snail and other molluscs, Tauc[4,5] has recently described postsynaptic inhibitory potentials, and inhibitory effects of long duration, which might be relevant in an interpretation of the mechanism of habituation

Our experiments were performed in an isolated nervous system preparation of the land snail (*Helix*) The whole periœsophageal ring of nervous ganglia and commissures, together with the mantle nerves, was cut loose and partially desheathed It was mounted in a 'Lucite' chamber and covered with Cardot's solution The mantle nerves were threaded through small holes into a neighbouring chamber, and mounted on bipolar platinum–iridium electrodes and covered with mineral oil Intracellular electrical recording was carried out with conventional glass micropipettes filled with 2 5–3 *M* potassium chloride

In the course of exploratory recording of the electrical activity of different cells in the parietal ganglia, we concentrated our observations on a group of two or three big cells (150–225μ in diameter) at the medial side of the right parietal ganglion, just left of the root of the internal right mantle nerve We selected these cells because of their size, easy recognition, and stability of response (a couple of hours)

When a micropipette penetrates the cell membrane, a resting potential of 40–60 mV is recorded, with an occasional burst of spikes After some minutes of impalement, these neurones exhibit a low-frequency discharge of impulses, with slow and irregular changes in frequency, or with alternating periods of activity and silence We speak of this as 'spontaneous' activity not prejudging if it is due to random synaptic bombardment or autorrhythmic activity generated in the impaled cell itself Not only full-sized spike potentials (with an overshoot of 20–40 mV) but also abortive or incipient spikes, and slower or faster oscillations of the membrane potential, in a depolarizing or hyperpolarizing direction, may be recorded

If the ipsilateral mantle nerve is stimulated with electrical pulses at rather low frequencies (1–5 sec.$^{-1}$), each stimulus may at the beginning drive a full-sized spike potential in the neurone (Fig 1) After a certain number of stimuli, both the driven responses, and the 'spontaneous' impulses as well, are blocked and replaced by an oscillating type of hyperpolarizing activity, which either builds up gradually during stimulation or appears abruptly after some stimuli. In many cases, with adequate amplification and time base, each afferent impulse can be seen to be followed by a hyperpolarizing potential with quite a regular latency These hyperpolarizing effects have been

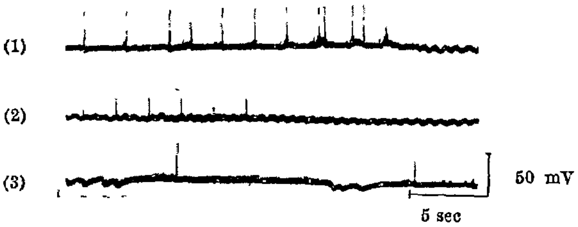

Fig 1 Electrical activity of snail ganglion cell (continuous record except for 18 sec cut between (2) and (3)) (1) Neurone discharges 'spontaneously' Stimulation of ipsilateral mantle nerve at a frequency of 5/sec 'Driven' spikes, preceded by slight positive potentials, can be observed after the first seven stimuli Spike activity is then blocked, being replaced by oscillating hyperpolarizing potentials These continue despite cessation of stimulation, for 40 sec, before a 'spontaneous' spike reappears (2)–(3) (3) Full-sized spikes intermingled with incipient spikes and positive potentials

recorded both with ipsilateral and contralateral stimulation In some instances the inhibitory effects are established after some stimuli, but without the remarkable oscillating behaviour already described

When stimulation is discontinued, hyperpolarizing oscillations and inhibitory effects gradually subside, and after 20–100 sec, 'spontaneous' activity reappears, the membrane potential shifts towards negativity, positive potentials may appear intermingled with full-sized or incipient spikes, until the resting pattern of activity is finally re-established (Fig 1) After some minutes of rest, renewal of stimulation is followed by earlier inhibitory effects, block being obtained with fewer stimuli, and eventually with a single stimulus These blocking effects of long duration, especially when correlated with hyperpolarizing responses, suggest a mechanism different from fatigue—rather a mechanism of active inhibition It is also improbable that fatigue could result from such a low frequency of stimulation, on occasions lower than the frequency of 'spontaneous' activity itself

It is rather difficult to justify the use of the term 'habituation' to describe our observations, because of the conditions in which the experiments were carried out—with an isolated nervous system preparation, electrical stimulation of nerve trunks, and the short period of observation possible Nevertheless, they confirm the existence of an inherent inhibitory mechanism in the nervous system of the snail, a mechanism which, put into action by repeated stimulation, could be the basis for a process analogous to habituation, at the neuronal level Finally, as our observations seem to conform so neatly with Moruzzi's vivid suggestion regarding the mechanism of habituation, namely, that "monotonous repetition of an identical stimulus would bring about, by a phenomenon of temporal facilitation—an avalanching increase of activity in inhibitory neurons", we communicate these results under this rather provoking title, and as a schematic model for describing the phenomenon of habituation and discussing its hypothetical mechanism

Effects of Intensity of Driving Stimulus on the Shape of Membrane Action Potential of the Heart

An investigation of the influence of driving stimuli on the membrane action potentials of toad cardiac muscle fibres has been made Endocardial surfaces of excised hearts were exposed and the transmembrane potentials of atrial and ventricular fibres recorded by means of glass-pipette microelectrodes.

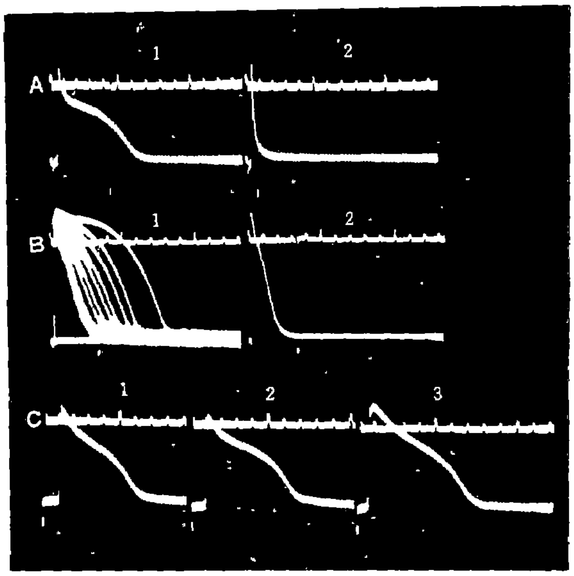

Fig 1 *A*-1, Duration of action potential of an atrial fibre when using a threshold driving stimulus (7 V), and *A*-2 the change in duration when driving stimuli were of twice threshold strength *B*-1, The progressive shortening of the action potential when driving of quiescent atrial fibres was begun—the first ten beats *B*-2 shows the steady state attained *C*, Control atrial fibre action potential (1), after atropinization (terminal concentration of 1 in a million) (2), and when twice threshold driving stimuli were used on the atropinized tissue (3) Time is indicated in 100 (small pips) and 500 (large pips) msec intervals Calibration of voltage on the left base indicates −100 mV from the extracellular potential (time-base)

As shown in Fig 1*A*, duration of the action potentials of atrial fibres was reduced from 500 msec to 59 msec or by 88 per cent, when the intensity of the driving stimulus was made twice the threshold strength (Fig 1 *A*–2) This effect was reversible and could be reproduced at will Thus, by properly adjusting the intensity of driving stimuli the duration of induced action potentials could be controlled

It was occasionally observed that similar changes in duration occur without the use of supraliminal stimuli When atrial fibres, which had been quiescent for some time (about 2 min), were driven with threshold stimuli, the action potential shortened progressively (Fig 1 *B*–1) and attained a steady state of duration at about 22 per cent of the initial duration (Fig 1 *B*–2) that of the first driven response

Shortening of the duration of the action potential brought about by the procedure mentioned above was quite similar to the effect of acetylcholine or vagal stimulation All three effects were antagonized by atropine These findings suggest that a substance like acetylcholine is liberated by the driving stimulus and that the amount of the substance discharged is increased with an increase in the intensity of the stimulus

In both atrial and ventricular fibres, the degree of reduction brought about by an increase in the intensity of driving stimuli was almost the same as that caused by maximal vagal stimulation This result and the fact that the reduction was not uniform around the driving cathode suggest the possibility that liberation of acetylcholine occurs from intramural nerve endings or ganglia stimulated directly by the electrical drive itself

The next problem is whether or not autonomimetic substances other than acetylcholine are also liberated by driving stimuli The duration of the action potential elicited by threshold driving stimuli was prolonged to some extent by administration of atropine (Fig. 1 *C*–2). After atropinization, increase in the intensity of driving stimuli still brought about certain changes in shape of the action potential, namely, a prolongation of its duration, rather than a shortening, an increase in amplitude of the overshoot, a slowing of the terminal phase of depolarization and initial phase of repolarization (Fig. 1 *C*–3). Since similar effects were obtained both in atrial and ventricular fibres by administration of epinephrine or norepinephrine as well as by sympathetic nerve stimulation, it is conceivable that increase in the intensity of the driving stimuli results in liberation of a sympathomimetic substance. This liberation might result from stimulation of intramural nerve fibres by driving stimuli as in the case of liberation of acetylcholine. In preparations not atropinized, these effects were not observed, probably because they were masked by those of the acetylcholine which was simultaneously liberated.

It is obvious that in electrically driven hearts the duration and shape of the membrane action potential can be widely varied, depending on the intensity of the driving stimuli. The possible liberation of the autonomimetic substances should always be taken into account in interpreting the results of experiments which involve electric stimulation of cardiac tissue.

Interrelationship between Fat and Sugar Metabolism in Infant Rats

Rat milk contains a large amount of fat and protein[1]. The amount of sugar in this food is just sufficient to cover the energy needs of the infant rat for about 2 hr., and it is thus obvious that the energy required for the remaining 22 hr. of the day must come either from fat or protein. This is underlined by the fact that liver and muscle glycogen content, although falling transiently shortly after birth, soon return to higher levels[2].

In order to gain further insight into the ways in which individual nutrients are utilized by the infant rat the following experiments were performed. Rats aged 5 (suckling period) and 30 days (end of weaning) and adult animals (body-weight 200 gm.) of both sexes were starved for 24 hr., the 5-day-old animals at 30° C., the older ones at room temperature. They were then given 1·1 ml. of olive oil/100 gm. body-weight via a stomach tube, and were killed at different intervals. Liver glycogen content[3] and blood glucose-levels[4] were determined. It is evident from Fig. 1 that administration of olive oil to animals aged 5 days resulted in a rapid increase in the level of liver glycogen, while no such rise was observed in animals aged 30 days, or in adult rats. Blood glucose-levels remained unchanged in all age-groups.

The administration of 1·1 ml. oleic acid/100 gm. body-weight to 5-day-old rats resulted in a much smaller, and variable, rise in liver glycogen content and the blood glucose-level was slightly raised.

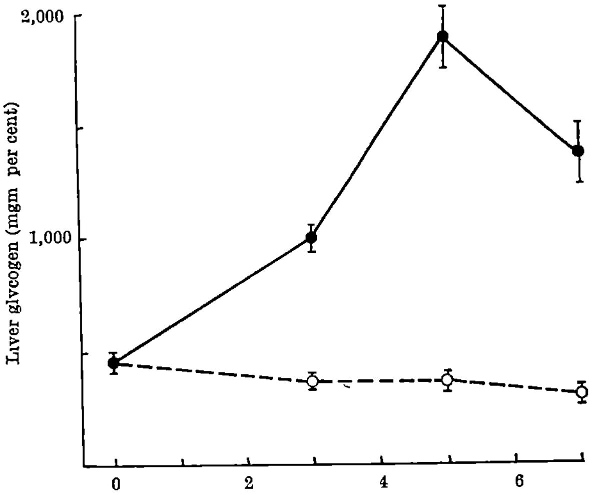

Fig. 1. Liver glycogen content in rats starved for 24 hr. and then given 1·1 ml. olive oil/100 gm. body-weight via stomach tube. Full line, rats aged 5 days, interrupted line, rats aged 30 days (the same type of curve was obtained for adult animals and for 5-day-old rats not given oil). Vertical lines indicate standard errors, each point is the average of at least 8 rats

It thus appeared that the glycerol contained in olive oil was responsible for the large rise in liver glycogen content found in 5-day-old rats. Administration of 2 ml. of a 2·5 per cent glycerol solution per 100 gm. body-weight, or administration of a mixture of oleic acid and glycerol corresponding to 1·1 ml. olive oil/100 gm., however, did not cause a rise in liver glycogen content, although hyperglycæmia was regularly found.

These results may be explained in several ways. Either fat gives rise to carbohydrate or fat spares sugars to a greater extent in the younger age-group. The first possibility can be rejected on theoretical grounds[5]: the second, however, may also be objected to since, following olive oil administration, glycogen accumulates in the liver and must be synthesized from some substance other than protein or amino-acids following the finding that gluconeogenesis from casein hydrolysate is much lower in sucking rats than in older animals[6]. Finally, there remains the possibility that triglycerides are transported differently in infant rats, as is also indicated by other results[7], and are transferred across the intestinal wall as such and broken down elsewhere, the glycerol being used for synthesis of liver glycogen.

Generalized Skeletal Response on Local Trauma in Young Rats studied by means of ^{45}Ca-Metabolism

In connexion with following-up deviations in metabolism of calcium in bones in young animals after local injury by Roentgen irradiation, we wished to be convinced about the effect of other kinds of physical traumatism on the metabolism of calcium in bones For this purpose we chose electric current for several reasons in the first place, almost nothing is known about deviation in metabolism of bones injured by electric current, and secondly, because the entire question of the effect of such trauma on bones has been relatively little studied Electro-trauma is quite easily carried out It is also known that the majority of wounds in electro-trauma quickly heal without suppuration so that when experimenting it is possible to exclude undesired suppuration as a complication which could misrepresent the observed results In case of other surface injuries, for example, radiation damage, torpid ulcers arise which are the seats of infection, causing local irritation which may meet with a response in the entire organism

In our experiments we used male rats of the Wistar strain about 10 weeks old, each weighing 120–130 gm We wounded them in the upper part of the shank on the back right limb by discharging a condenser, the capacity of which was 80 μF , loaded at a potential of 2,000 V

Thus only one discharge penetrated across the limb The rats were then divided into groups of five, and 20 μc of $^{45}CaCl_2$ in 1 ml physiological salt solution were applied intraperitoneally after 4, 10, 17, 24 and 38 days after injury The rats were killed 48 hr after addition of the isotope, and the tibias of the injured limbs dissected The control limbs of the injured animals and the tibias of a control group of animals treated with isotope but not subjected to electro-trauma were also removed Besides the tibia, we also took out the shoulder blade of all animals With all the bones we recorded the weight of the dry bone and the ash after burning, measured the entire contents of bone calcium, and determined the specific activity of the calcium-45

Four days after the injury, differences appeared in the weight of the dry bone, ash and calcium content of the tibias of the injured animals in comparison with the control group (Fig 1) All values showed a tendency to fall, followed by a much slower incline and restitution than in the uninjured animals At the same time certain differences in weight appeared even in uninjured limbs of wounded animals, showing that a general reaction results from a local trauma These changes occurred not only on the bones of the limbs but were also evident on the scapula, which is a bone of differently growing type from that of the limb, and is situated far from the injured place

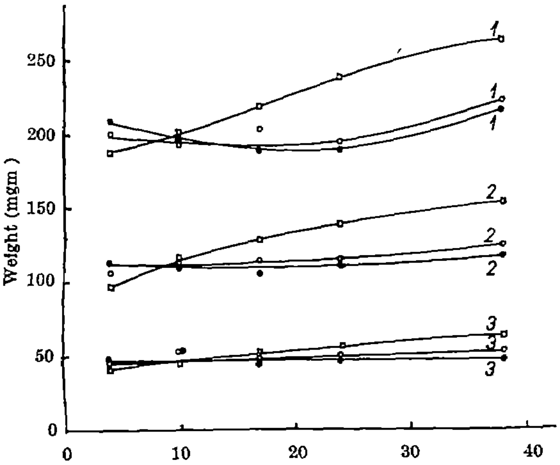

Fig 1 Weight of dry bone (1), ash (2) and total bone calcium (3) of rat tibias □, Control group, ○, traumatized tibia, ●, non-traumatized tibia

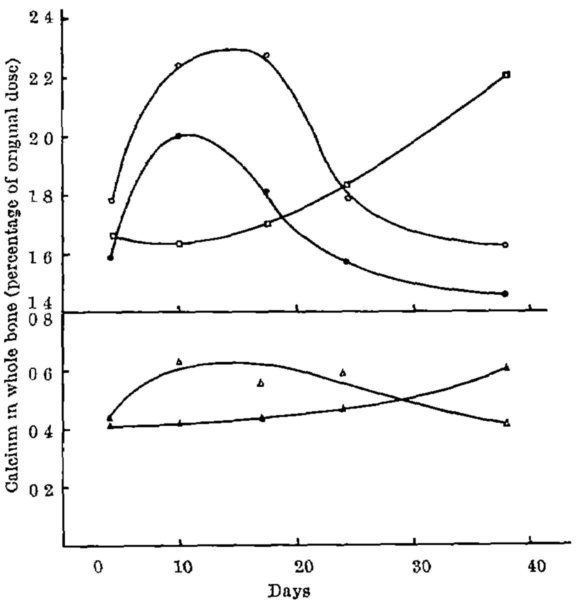

Figs 2 and 3 48-hr accretion of calcium-45 in the tibia (above) and scapula (below) □, Tibia in control group, ○, traumatized tibia, ●, non-traumatized tibia, ▲, scapula of control group, △, scapula in traumatized animals

Distinct and important changes are evident when tracing the specific activity by measuring the values of calcium-45 in injured and uninjured bones Fig 2 shows the 2-day accretion of calcium-45 in the tibia and Fig 3 in the scapula It shows that in the bones of injured animals an increased accretion of isotope at first took place in all bones, again indicating the general response of calcium metabolism in the skeleton When comparing Fig 1 and the weights, it is surprising to find that while the weight of dry bone, ash and total bone-calcium content show a decline, the specific activity increases

Calcium metabolism depends on a number of factors[1–4] the most important of which are accretion, resorption and calcium exchange In comparing the results of our experiments, which follow accretion for 2 days, changes are evident in accretion values of calcium-45 in injured and uninjured bones of the experimental animal, changes which are expressions of local and general reactions as a result of local traumas In comparing the results with the values of weight, it is shown that, after injury, not only the accretion is increased, but also the resorption of calcium (even more than accretion), so that the injury causes deep interference in the metabolism of calcium in the entire skeleton

One other interesting inference, which follows from measuring and observing these values, is that in young animals even at the end of the experiment (about 40 days after injury) the conditions of metabolism had not become normalized Although the skin wounds after electro-trauma were healed without complications within ten days of the injury—healed in such a way that no traces of the transit of current were seen macroscopically—the disturbance of calcium metabolism and the response to local trauma remains as is shown by the dry-weight, ash, and calcium content of measured bones Hence, the metabolic changes which result from local injuries to growing organism can persist for some time after healing. A similar reaction was noticed not only after electro-trauma injury, but also as a result of radiation injury[3], showing that this general response is the natural reaction of growing organisms to local trauma

Details of the conditions of accretion and resorption of radiocalcium after local electro-trauma has been published in *Archiv fur orthopadische und Unfall-Chirurgie*[5]

Number of Recirculations of Chick Embryo Erythrocytes

It has recently been shown by Allison[1] on the grounds of cardiac output × erythrocyte life-span/blood volume that in spite of quite different erythrocyte life-spans in man, dog and rat the average number of times an erythrocyte is oxygenated and deoxygenated, that is, the number of recirculations, is in all three species of the same order, about 180,000 times It might be of interest to determine if this relation is valid for embryonic erythrocytes also, and for their various lines respectively Unfortunately, only incomplete data or none at all are available for mammalian embryos, though values covering nearly the whole incubation period have been published for chick embryos

Using Allison's formula it was found that the number of recirculations of nucleated adult hen's erythrocyte is between 147,150 and 186,300, that is, in the range valid for non-nucleated erythrocytes of adult mammals[2]

Allison's formula in its original form is generally not suitable for calculation of embryonic erythrocyte recirculations because the cardiac output and the increase in blood volume and the absolute number of erythrocytes of one generation changes as development proceeds For this reason we suggest the following procedure for each day of incubation the number of recirculations is multiplied by the corresponding absolute number of erythrocytes of one line present in circulation (taken from their survival curve) The sum of these products over the whole incubation period will be divided by the maximal number reached by the erythrocyte line during incubation Thus the average number of recirculations one erythrocyte undergoes will be obtained

For each day of incubation starting with the second, the number of recirculations was calculated from Hughes's[3] data for stroke volume (data published by Hughes are for both ventricles together, and must therefore be gradually reduced starting with the fourth day to one-half from the seventh day onwards because of the development of allantoic circulation) multiplied by heart-rate value[4] The product yielded the cardiac output/min Thereafter the cardiac output values were multiplied by 1,440 min (24 hr) and divided by the corresponding blood volume[5]. So the average number of recirculations of the entire circulating blood/day of development was estimated The average number of recirculations in a day's interval increase from 362 between the second and third day of incubation to 6,145 between hatching (20th day) and the first post-embryonic day (Fig 1*a*) Because the results on the stroke volume[3] cover the period from day 2 5 to day 17 only, the border values on both sides have had to be extrapolated (dotted line in Fig 1*a*). The error of this extrapolation is, however, of little bearing because the corresponding values in both survival curves (Fig 1*b*, *c*) are low

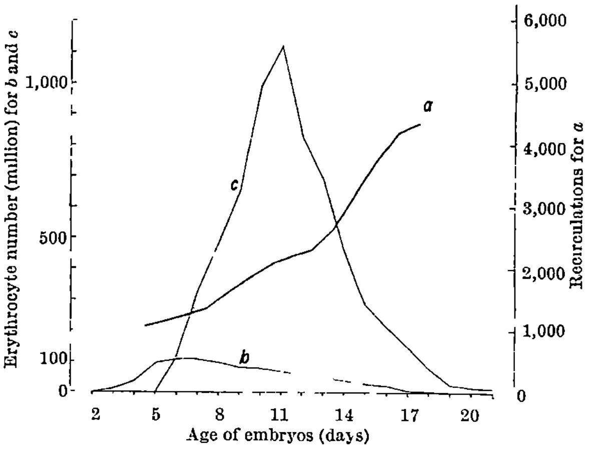

Fig. 1 (*a*) Number of recirculations from the second day of incubation until the first postembryonic day, survival curves of primitive (*b*) and definitive erythrocytes with round nuclei (*c*) during the same period

Both survival curves (absolute number of erythrocyte lines concerned present in circulation) are approximately of triangular shape and are practically limited to the embryonic period That of the primitive erythrocytes[6], the first generation of erythrocytes (E I) starts on the second day of incubation with a maximum on the seventh day, while that of the definitive erythrocytes with round nuclei[7], the second generation of embryonic erythrocytes (E II$_1$), which appears as late as on the fifth day, reaches its maximum on the eleventh day

From these results the average number of recirculations for a primitive erythrocyte was calculated to be 14,452 and quite a similar number (13,935) was found for a definitive erythrocyte with round nucleus These values are most probably maximal, because the data for stroke volume probably err, according to Hughes[3], on the high side That means that the average number of recirculations of two generations of chick embryo erythrocytes is considerably lower than in hens. being less than 10 per cent of adult values This is not proportioned to the ratio of average erythrocyte life-spans concerned—30 days in hens[8] as compared with 8 5 days[6] for E I and 5 7 days[7] for E II$_1$ respectively in chick embryos. This indicates that there will be perhaps some other factor or factors besides that of the metabolic wear connected with ionic fluxes across the erythrocyte membrane as suggested by Allison, which play their part in the extremely short life-spans of chick embryo erythrocytes. One of these factors might be the high degree of immaturity at which the chick embryo erythrocytes are poured out into the blood stream[9].

A full account of our calculations is to be published elsewhere[2].

Future investigations will show if this relatively small number of recirculations holds good also for mammalian primitive erythrocytes. There are indications that their average life-spans are also about one-quarter of that found in adult mammals[10].

PHARMACOLOGY

Stimulation of Uptake of Calcium-45 in the Adrenal Gland by Acetylcholine

RECENTLY, Douglas and Rubin[1] have suggested that acetylcholine, the physiological transmitter of sympathetic nerve effects at the adrenal medulla, evokes catecholamine secretion by causing calcium ions to penetrate the medullary cells. Our experiments with calcium-45 have now provided further evidence consonant with this idea.

Adrenal glands from nine cats were perfused *in vitro* with Locke's solution. One gland from each animal was used to determine 'resting' uptake of calcium and the contralateral gland stimulated with acetylcholine. Both glands were perfused with Locke's solution containing calcium-45 for about 10 min during which time one was given acetylcholine in a concentration (10^{-5} gm./ml.) sufficient to cause a brisk secretion of catecholamines. Thereafter, they were perfused with Locke's solution containing only calcium-40 and measurements were made of the efflux of calcium-45. Loss of calcium-45 from the perfused glands was at first very rapid, but it slowed after about 50 min and the decline in activity in the glands thenceforth followed a simple exponential course. It was assumed, on the basis of the work of others on muscle[2,3], that by this time the extracellular calcium-45 had been completely washed out. One hundred minutes after beginning the washout, stimulated and unstimulated glands were separated into medulla and cortex and their radioactivity determined.

The glands exposed to acetylcholine contained more radioactivity than the unstimulated glands. On a weight basis, the medulla was several times more active than the cortex. Comparison of the stimulated and 'resting' medullæ indicated that during perfusion with acetylcholine the rate of calcium uptake was increased about eight-fold. A number of similar experiments were carried out with potassium, which is also known to evoke adrenal secretion. Potassium (56 m*M*) also caused an increased uptake of calcium-45, with the medulla again showing the greatest rate of uptake. This stimulant effect of potassium on calcium influx persisted in the presence of hexamethonium sufficient to suppress indirect effects due to stimulation of nerve endings present in the gland, and was presumably due to depolarization of the medullary cells.

We observed incidentally that acetylcholine and potassium also increased the rate of uptake of calcium-45 by the cortex, although to a lesser extent. This effect was too great to be accounted for by incomplete separation of medulla from cortex. It may be related to a stimulant effect of acetylcholine on adrenocortical secretion, such as Rosenfeld[4] observed in perfused calf adrenals.

The finding of increased uptake of calcium during exposure to acetylcholine or potassium is consistent with the idea that acetylcholine evokes catecholamine secretion by causing calcium ions to penetrate the adrenal medullary cells and that this penetration may be brought about by depolarization[1]. The finding also extends the remarkable parallelism previously noted[1] between the two sets of evidence implicating calcium in 'stimulus-secretion coupling' at the adrenal gland and in 'excitation-contraction coupling' in muscle.

Pharmacodynamical Effects of Asarone and β-Asarone

DANDIYA *et al.*[1,2] have determined the effect on the central nervous system of *Acorus calamus*, a drug used in the Indian system of medicine for various ailments including some of the mental disorders. In the present work two fractions 'asarone' and 'β-asarone' (isolated by Baxter and Kandel) of the volatile oil of *Acorus calamus* have been investigated with regard to effects on the central nervous system and other pharmacodynamical actions which these drugs have.

The prolongation of hypnotic activity of (i) pentobarbitone, (ii) hexobarbitone, and (iii) ethanol was investigated in white mice. Asarone and β-asarone were given in different groups of animals intraperitoneally in doses of 50 mgm./kgm., followed 15 min later by one of the anæsthetic agents mentioned. The sleeping time was recorded in the manner described in refs. 1 and 2. It was observed that both asarone and β-asarone significantly ($P < 0.01$) prolonged the sleeping time of all the anæsthetic agents mentioned, for example, the mean sleeping time due to pentobarbitone alone, of 101.6 ± 14.5 min., was raised to 254.5 ± 18.8 min. when the animals were pretreated with β-asarone and to 206.4 ± 28.3 min. when the animals were pretreated with asarone.

It was also observed that the hypnotic potentiating property of β-asarone was significantly more ($P < 0.05$) than that of asarone in these doses against all these anæsthetic agents. Asarone or β-asarone in these doses exerted no effect on the spontaneous motor activity of the animals in contrast to the increased motor activity observed with all the anæsthetic agents mentioned However, the spontaneous activity of untreated animals was definitely reduced by asarone or β-asarone

Both these agents caused a significant fall in rectal temperature of mice ($P < 0\ 01$) The fall was maximum in the first 30–45 min and lasted 2–3 hr and the recovery to the normal was attained in about 5 hr

Anticonvulsant action of asarone and β-asarone was studied in ninety albino rats Convulsions were induced by electro-shocks, or 'Metrazol' or 'Picrotoxin' It was seen that β-asarone in an intraperitoneal dosage of 20 mgm /kgm failed to influence the electro-shock seizures Asarone in a dose of 20 mgm / kgm intraperitoneally caused reduction in the incidence, duration and severity of extensor tonic phase induced by electric shocks Asarone in a dose of 50 mgm /kgm gave protective action against shocks induced by 'Metrazol' when prevention of extensor tonic spasm and death were considered as the protective end-points The occurrence of both these end-points was markedly reduced in animals treated with asarone β-asarone, on the other hand, potentiated the lethal action of 'Metrazol' However, both the compounds potentiated convulsions induced by 'Picrotoxin' β-asarone itself in 50 mgm /kgm doses intraperitoneally caused mild generalized myoclonic convulsions in rats, this property was lacking in asarone

Effect on the spontaneous behaviour pattern was studied in eight cats according to the method in ref 3 Both these compounds reduced the sociability score Similar results were obtained with other tranquillizers like reserpine and chlorpromazine The influence on conditioned escape and avoidance responses on 44 rats was investigated The rats were trained to develop these two reflexes by the method in ref 4 (with slight modifications) It was seen that the escape phenomenon (the rat jumping out of the cage even before the presentation of the conditioned stimulus, namely, bell) was abolished in 25 per cent of the trials and conditioned avoidance behaviour was abolished in 10 per cent of the trials, after both asarone and β-asarone This percentage loss in these two reflexes was significant as compared with control data

Frog heart perfusion experiments revealed that both asarone and β-asarone cause stoppage of heart in diastole in quite low concentration However, β-asarone appeared to be more potent than asarone

Isolated pieces of rabbit intestine were fixed for investigating the influence of these compounds on the longitudinal movements and the tone of the intestine It was seen that both asarone and β-asarone reduced the tone and caused diminution in the longitudinal movements β-asarone was found to be much more potent than asarone Rhythmicity of the isolated uterine strip was reduced by both these agents

Anti-acetylcholine actions for both these agents were investigated on the following preparations (1) isolated guinea pig ileum, (2) isolated uterine strip of rat, (3) dog's tracheal muscle preparation, and (4) frog rectus Both asarone and β-asarone were found to have anti-acetylcholine actions on these preparations and here, too, β-asarone was more potent than asarone

So both asarone and β-asarone possess many pharmacodynamical actions quite similar to some of the well-established tranquillizers β-asarone appears to be more potent than asarone and the influence of these compounds on electro-shocks and 'Metrazol' shocks differs β-asarone itself causes generalized convulsions and potentiates the 'Metrazol' seizures, while asarone has a definite tendency to protect against 'Metrazol' convulsions and modify electro-shocks

The investigation was partly financed by the Indian Council of Medical Research, New Delhi

HÆMATOLOGY

Haptoglobin and Transferrin Types in Peruvian Indians

RECENT reports on the incidence of the serum haptoglobin types of American Indians have included observations on natives of Alaska[1], south-western United States[2,3], southern Mexico and Guatemala[4], Venezuela[5], and Chile[3] The incidence of the Hp^1 gene, shown in Table 1, is usually higher than that found in the population of western Europe[4] (gene frequency 0 32–0 43, mean about 0 39) In several tribes, the occurrence of Hp^1 is as frequent as that reported in the various Bantus of Africa[4] (0 49–0 87) This finding is of particular interest when compared with the low incidence of Hp^1 (0 09–0 28) in Asiatic populations[2,6] Since genetic drift is often responsible for marked fluctuations in the concentration of given genes in comparatively isolated areas, more observations are necessary to confirm these apparent differences We have investigated the haptoglobin (and transferrin) types of two Peruvian Indian groups

Plasma specimens were obtained from 56 Aymara-speaking Indians of Jaillihuaya, who have little, if any, European or African admixture, and an additional

* No visible haptoglobin, or unclassified
† Includes two examples of *Hp* 2–1 (mod)

117 specimens from the Quechua-speaking Indians of Paucarcolla From work on their blood groups, these subjects were calculated to have a White admixture of about 1 1 per cent and a Negro admixture of about 14 6 per cent[7,8], although no aberrant hæmoglobins or deficiencies in glucose-6-phosphate dehydrogenase were encountered[9] The details of collection and distribution of samples have already been described[8]

Starch-gel electrophoresis was performed by Smithies' method[10], using Poulik's discontinuous buffer system[11] and a staining procedure outlined elsewhere[12]

No difficulties in interpreting the haptoglobin patterns were encountered, since all specimens contained adequate quantities of the hæmoglobin-binding protein

There were no unusual phenotypes, such as the *Hp* 2–1 (mod) type which is a characteristic of 10 per cent of American Negroes[13]

Transferrin phenotype *C* was found in all the subjects except one, whose phenotype was B_2C Transferrin CD_1, which occurs in about 10 per cent of American Negroes[14], and the recently described $B_{0-1}C$ type[3], found in about 8 per cent of Navajo Indians, were not encountered

The haptoglobin phenotype distribution in the two Peruvian groups is compared in Table 1 with data on other Indians of North, Central and South America The marked elevation in Hp^1 gene frequency cannot be considered to be due to Negro admixture in the Aymara-speaking Indians, and Negro admixture could only account for a moderate degree of elevation in the Quechua

It has been suggested[4] that an increasing frequency of the Hp^1 gene in native populations occurs in the following order Asia, Alaska, North America, Central and South America That this apparent cline might reflect some regional selective advantage(s) is an attractive hypothesis. Further work on these and other populations may eventually lead to the elucidation of mechanisms responsible for the maintenance of haptoglobin polymorphism throughout the world

This work was supported, in part, by U S. Public Health Service Grant *H*-5780.

Serological Evidence of a Chromatographic Sub-fractionation of Human 7S γ-Globulin

PREPARATIONS consisting of the electrophoretically slowest migrating part of the 7*S* γ-globulin were prepared by means of preparative zone electrophoresis Individual preparations were obtained from normal serum and from the serum of an *Rh*-immunized individual Preparations from pooled plasma were obtained from commercially available Cohn fractionated γ-globulin (supplied by AB KABI, Stockholm) All preparations showed *Gm*(*a*+) character when tested in a serum-grouping system according to Grubb[1,2]. On immunoelectrophoresis with different rabbit antisera against human whole serum (supplied by Behringwerke, W Germany) the γ-globulin preparations showed the character of 7*S* γ-globulin No β_{2A} or β_{2M} was present

These 7*S* γ-globulin preparations were subjected to hydroxyl apatite chromatography according to Hjertén[3]. The protein preparations dissolved in 0 02 mole phosphate buffer, *p*H 7 9, were applied to columns equilibrated with the buffer The protein was eluted with the same buffer by a stepwise increase of the molarity of 0 03–0 65 As a rule all the protein was eluted in the steps up to 0 09 *M* After dialysis against buffered saline (*p*H 7 2) and adjustment of the sample by ultrafiltration to equal protein concentration (as determined by a modified Folin method and by the Kjeldahl method), the sub-fractions were analysed and compared in the following way

Immunoelectrophoresis revealed a somewhat higher electrophoretic mobility of the fractions eluted by phosphate buffer of lower molarity than of fractions eluted at higher molarity Furthermore, the former type of γ-globulin showed a double precipitin line consisting of two discrete parallel lines, while the latter type showed a sharp single precipitin line (cf Heremans[4]) This difference was more or less pronounced depending on which antiserum was used

As already pointed out the γ-globulin starting materials used in the experiments were known to inhibit agglutination in a *Gm* grouping test system This activity was now tested in the sub-fractions obtained by the hydroxyl apatite chromatography The agglutinating system used consisted of constant amounts of *O Rh*(+) human red cells sensitized by incomplete *Rh*-antibodies and a rheumatoid serum of anti-*Gm*(*a*) character The γ-globulin sub-fractions, of equal protein concentration, were added in two-fold serial dilutions to the agglutinating system In all cases a higher agglutination-inhibiting activity was

* To an agglutinating system consisting of *O Rh*(+) red cells sensitized by incomplete anti-*Rh* antibodies and diluted rheumatoid arthritis serum of anti-*Gm*(*a*) character two-fold dilutions of the different *S* 7 γ-globulin sub-fractions were added

† A constant amount of *O Rh*(+) cells was added to two-fold dilutions of the different 7 *S* γ-globulin sub-fractions After incubation at 37° for 2 hr and subsequent washing, the agglutinability of the cells was tested with a rabbit anti-human γ-globulin serum and with the anti-*Gm*(*a*) rheumatoid arthritis serum

found in the sub-fractions eluted by buffers of higher molarity than in fractions eluted by buffer of lower molarity. In the different experiments, the largest difference in this respect between sub-fractions originating from the same γ-globulin preparation varied 2–5 titre steps.

The possibility that this difference could be explained by an enrichment in the more active sub-fractions of aggregated 7*S* γ-globulin, which may have a high agglutination-inhibiting activity in the *Gm* grouping test system[5], was excluded by the following experiment. γ-Globulin sub-fractions obtained by hydroxyl apatite chromatography were submitted to zone ultracentrifugation in a sucrose gradient. The top fractions in this way freed from any fast-sedimenting 7*S* γ-globulin aggregates were recovered and tested in the *Gm* grouping system. The same difference in agglutination inhibition was observed as before ultracentrifugation.

The serological investigation of the γ-globulin sub-fractions of the serum containing incomplete *Rh*-antibodies is shown in Table 1. Besides the differences mentioned above, an enrichment of the *Rh*-antibodies in the sub-fractions eluted by buffer of high molarity was observed.

These observations thus indicate that hydroxyl apatite chromatography of human 7*S* γ-globulin may give sub-fractions differing in serological character.

PATHOLOGY

Intracellular Response to an Iso-immune Reaction at the Surface of Ascites Tumour Cells

THE cytotoxic effect on mouse ascites tumour cells treated *in vitro* with various antibodies has been shown to require the presence of complement[1,2]. In the absence of complement the cells appear to be normal when viewed by phase contrast microscopy[3], they retain their capacity to exclude trypan blue[3] and to metabolize glucose[4]. The only changes which have been reported are slight alterations in the fine structure of the cell surface, which were thought to favour agglutination by rabbit antibody directed against ascites cells[3].

There is strong evidence, from hæmagglutination work, that some iso-antigens of the *H*-2 system[6] are present on the surface of mouse erythrocytes[5]. The present investigation was undertaken to determine whether such iso-antigens could be demonstrated on the surface of *EL*4 ascites cells, and whether histochemical methods could be used to reveal the effect on the cell of an iso-immune reaction at its surface, in the absence of complement.

Iso-antisera were prepared in *BALB/c* strain mice against *EL*4 tumour cells resident in *C57BL* strain mice by immunization with tumour cells mixed with Freund's complete adjuvant. The mice and tumour were the generous gift of the late Dr. P. A. Gorer. The cytotoxic titres[2] of these antisera, in the presence of complement, varied from 1/64 to 1/256. In the absence of complement, iso-antibody caused negligible agglutination of cells even when present at as high a concentration as 1 vol. antiserum : 1 vol. cell suspension containing 2×10^7 cells/ml. This was in marked contrast to the strong agglutinating effect of rabbit antibody which was observable even with rabbit antiserum diluted 256 times.

It was first necessary to confirm that the mouse iso-antibody did react with surface antigens. This was effected by incubating suspensions of *EL*4 cells with mouse antiserum (preheated for 30 min. at 56° C.) in the absence of added complement. That the antibody was located exclusively on the cell surface was observed by subsequent staining of air-dried smears of washed cells with a rabbit anti-mouse globulin which had been conjugated with fluorescein isothiocyanate.

It was remarkable that in these circumstances, which were expected to produce purely surface effects, marked cytoplasmic changes were observed when histochemical techniques were applied to air-dried smears. Thus, exposure of the cells to iso-antiserum alone, at 37° C. for 15 min., in the absence of complement, resulted in marked activation of lysosomal acid phosphatase[7]; there was also simultaneous unmasking of cytoplasmic phospholipid, particularly in discrete granules, as shown by the acid hæmatin technique[8]. The stimulation of glucose dehydrogenase activity observed under similar conditions could have been a non-specific effect since it was also observed after incubation of these cells with normal serum.

The immunofluorescent results indicated that this iso-antibody acted solely at the surface of the cells under these experimental conditions. If this were true, then the effect of the immune reaction at the cell surface in causing changes in intra-cytoplasmic particles was surprising.

In homograft rejection, circulating antibody may act synergically with immunologically competent host cells, though the extent to which complement is involved is uncertain. It is possible that intra-cytoplasmic effects of iso-antibody acting at the donor cell surface may play some part in the mechanism of rejection.

A Carcinogenic Action of Testosterone, provoking Uterine Tumours in Mice

THE literature concerning the induction of tumours by hormones is very extensive[1-4]. Œstrogens especially appeared to play an important part in hormonal carcinogenesis[5]. Evidence of a carcinogenic action of androgens is very scant. Horning[6] observed 3 theca-cell ovarian tumours in rats and 2 adrenal cortical tumours in hamsters after long-term treatment with testosterone. Also, Kirkman[7] suggested that testosterone propionate may act as a non-specific carcinogen in the hamster.

In our experiments one pellet of 1–2 mgm. testosterone propionate was subcutaneously implanted into female mice of the $F1$ hybrid ($C57BL \times dba$) twice a week. The treatment was started at the age of 1½–3 months and continued until the mice had to be killed because of their bad condition.

At post-mortem examination a surprisingly high percentage of uterine tumours was found (Table 1).

Table 1. UTERINE TUMOURS INDUCED BY TESTOSTERONE

	No. of mice*	No. of mice with tumours	No. of mice with lung met.	Average survival time (months)†
♀♀ F_1 (*BD*)	14	6	3	18·8
♀♀ F_1 (*BDf*)	16	9	3	14·7
♀♀ F_1 (*BDf*)	12	11	4	15·3

* Surviving the testosterone treatment for 10 months or more.

† No difference was found in the survival time of the tumour-bearing and the non-tumour-bearing mice.

In 26 of the 42 mice treated with testosterone uterine tumours were observed, and in 10 of the tumour-bearing mice metastases were present in the lungs.

Most of these tumours were found either in the uterine cervix or in the unpaired uterine part. Only a few tumours were located in the horns of the uterus. The size of these tumours varied considerably. The largest diameter was about 25 mm. and the smallest 4 mm. The tumours were always strictly limited to the uterus and the vagina and no other tissue of the peritoneal cavity was involved. The surfaces of the cut tumours showed mostly a pink colour, but sometimes necrotic or hæmorrhagic areas were seen.

The histological pattern of the testosterone-induced uterine tumours was very characteristic and similar for the several tumours we have observed. In most of these tumours large trabeculæ of cells were found next to more solid parts. The trabeculæ formed locally branched papillæ inside large sinuses. Most of the tumour cells had a diameter varying from 20 to 30µ and contained an abundant fine granular cytoplasm which stained mostly basophilic. The nuclei were large and relatively clear with prominent nucleolus (Fig. 1).

Most of the tumours showed an infiltrative growth in the muscular layers of the uterine wall. This fact together with the appearance of lung metastases are distinguishing marks of the malignancy of these tumours.

In most of the mice bearing a uterine tumour as well as in those without a gross uterine tumour one or more small pink nodules were observed in the uterus. Macroscopically and microscopically these nodules showed close similarities to the gross uterine tumours. We think we are justified in considering these nodules as stages preceding the malignant uterine tumours.

These nodules developed in the stroma of the endometrium. The epithelium and the muscular layers were not involved. The origin and the histological aspects of the nodules are similar to the histological changes in the stroma of the endometrium during the first stages of pregnancy. On these similarities we base our hypothesis that the uterine tumours induced by testosterone are related to the decidua cells. The histological characteristics of these specific uterine tumours differ from the uterine carcinomas and uterine sarcomas so far described.

Deiodination of Thyroxine-^{131}I in Tumour-bearing Rats

IT has been shown that hyperthyroidism induced by the administration of large doses of triiodothyronine increased the radiosensitivity of tumours in rats and in human beings[1,2]. Later it was found that hyperthyroidism induced in this way significantly enhances the growth of a solid non-metastatic myeloid leukæmia tumour of the Sprague–Dawley rat, a rat fibrosarcoma of a local strain and the Ehrlich mouse ascites tumour[3].

In view of the profound effect of severe hyperthyroidism on tumour growth and its response to radiation, it became of interest to investigate the turnover of thyroxine in animals bearing these tumours.

The rate of deiodination of thyroxine was investigated by administration of a tracer quantity of labelled thyroxine and the amount of the inorganic iodide formed was determined by radioactive assay. To ensure complete retention of the iodide formed in the circulation, rats were surgically thyroidectomized 48 hr. before the turnover experiment. Tracer thyroxine, labelled with iodine-131 in the 3′ and 5′

positions, was injected into the vena cava following a bilateral nephrectomy. Blood samples were collected into heparinized test-tubes at 45-min. intervals for 5–8 hr. The serum was then separated and the iodine bound to protein was determined[4]. From the total values of serum iodine and protein-bound iodine the serum iodide concentration (per cent of injected dose per gm. serum) was calculated. The increase in iodide concentration with time was taken as an index of the rate of deiodination of thyroxine.

In the experiments performed on 150 rats it was found that the rate of deiodination (per cent thyroxine deiodinated per unit time) was higher in the animals bearing tumours than in the respective controls. Since age was one of the major factors affecting the rate of deiodination, all rats selected were of identical age. The differences between the average rates were 50 ± 10 per cent in the leukæmia tumour and 45 ± 10 per cent in the rats bearing fibrosarcoma, with a statistical significance of more than 99 per cent. In hypothyroid animals the difference in the rate of deiodination was even greater, amounting to 80 ± 15 per cent in the animals bearing fibrosarcoma as compared with their hypothyroid non-tumorous controls. In a similar manner old age was found to be another condition in which the difference between tumorous and control animals manifests itself emphatically; a difference of more than 150 per cent in the rates of deiodination was observed here. On the other hand, no significant difference in the rate of deiodination was found between animals with or without tumours in which hyperthyroidism had been induced artificially.

After the deiodination experiments the animals were killed and the specific activity of the tumours (per cent of injected dose per gm. tissue) was compared with that of the gastrocnemius muscle. The specific activity of the tumours was 3–5 times higher than that found in muscle and was comparable with that in the ovaries. A similar finding has been reported in the mouse mammary tumour using triiodothyronine[5].

The weights of the tumours ranged from 5 to 40 gm., constituting 2–25 per cent of the total weight of the rats bearing tumours. However, when the increase in rate of deiodination was related to the weight of tumour in each animal, or to the per cent body-weight constituted by the tumour, no correlation could be established.

Physiological variations between normal and tumour-bearing animals as described here are rare and are worth careful consideration. An increased rate of deiodination is generally associated with the hyperthyroid state, yet no indication of such a state is apparent in animals bearing tumours. As little is known about the mechanism of deiodination of thyroxine at the cellular level, it is premature to put forward an explanation for the enhanced deiodination.

The lack of correlation between the degree of enhanced deiodination and the mass of the tumour strongly suggest that the effect is due either to a change in the hepatic metabolization of thyroxine or to a certain factor of a systemic nature mediated by the presence of the tumour. The tumour thus does not appear to be the site at which the excess deiodination takes place. Should this effect prove to be associated with the presence of malignant tumours in general and should it occur also in human subjects afflicted with cancer, then the demonstration of an increase in the rate of deiodination of thyroxine may be of value for the early diagnosis of malignant growths which are not otherwise detectable.

HISTOLOGY

Role of the Thymus in Polysaccharide Metabolism

IT has been shown by a series of experiments[1-8] that the thymus plays an active and significant part in polysaccharide metabolism. It was demonstrated[1,3,4,8] that, unlike other lymphatic organs, stress and processes of tissue proliferation induced the emigration of cells from, and a mast-cell reaction in, the thymus. This reaction was preceded by the appearance of periodic acid–Schiff-positive cysts and of thymocytes containing periodic acid–Schiff-positive matter. It was possible to confirm these findings by demonstrating in tissue cultures[2] that the cells of the thymus showed a marked affinity for heparin[5] and decomposed heparin[2], which was much stronger than that of other cells (liver, spleen, heart, kidney) and even more pronounced than the heparin affinity of the lymph node, which ranks, in this respect, next to the thymus. Although these experiments revealed the prominent role of this organ in the metabolism of mucopolysaccharides, it seemed necessary to measure this activity by means of a more exact method.

It was with an indirect method and the use of isotopes that we investigated the correlation between thymus and acid mucopolysaccharides in the present experiments. Instead of labelled heparin we used labelled thionine (a dye): it combines with heparin *in vivo* so that radioactivity indicates the extent to which thionine is taken up by the organs and thus can be used as an indicator of their heparin metabolism. Thionine was labelled with sulphur-35 in our experiments for which 10 rats of 150 gm. body-weight were used. Each animal received intraperitoneally 4 mgm. of the dye. The animals were killed by a blow on the head 24 hr. after the injection; thymus, lymph node, spleen, liver and heart were removed, weighed and homogenized; radioactivity was then measured with an end-window Geiger–Müller tube and a scaler of type *EMG* 1872. Radioactivity in the blood was ascertained also. Results are shown in Table 1; values are given as percentages of total radioactivity introduced and refer to 100 mgm. of wet tissue.

Table 1

Organ	Radioactivity (percentage of total)	Standard deviation	Result of Student's t test
Thymus	2 52	0 18	Highly significant, $P \leqslant 0\ 1$ per cent
Lymph node	0 152	0 012	Highly significant, $P \leqslant 0\ 1$ per cent
Spleen	0 11	0 011	
Liver	0 12	0 003	
Heart	0 12	0 003	
Blood	0 007		

It can be seen that all tissues investigated, with the exception of the thymus and lymph node, took up approximately the same small quantity of dye This seems to indicate active uptake or the combination of the dye with the existing acid mucopolysaccharides, since radioactivity in the blood was quite negligible. Though quantitatively low, activity was significantly higher in the lymph node, and outstandingly high in the thymus, about 20 times as high as in other tissues

These figures are in good agreement with the results of earlier experiments· they show that the thymus plays a prominent part in the metabolism of acid mucopolysaccharides (of heparin in particular) and furthermore they show that although morphologically similar, the thymus on one hand, and the spleen and lymph node on the other, have different functions and are involved in different biological processes It seems, moreover, that as regards polysaccharide metabolism, there is also a difference between lymph node and spleen; this, too, is in agreement with earlier observations according to which the lymph node is more or less capable, and the spleen incapable, of forming mast cells[2,5]

Fixation of Muscle

I HAVE investigated recently the effect of various fixation methods on mammalian skeletal muscle For this purpose the biceps brachii muscle of the albino mouse was chosen because of its convenient size and the fact that it can be easily dissected out All the mice used were females weighing about 34 5 gm , the biceps muscles were weighed in each case, and all were found to weigh about 0 0155 gm

The fixatives used were of the normal concentrations, 2 per cent osmium tetroxide being used in Champy's fluid and in Flemming's fixative Following fixation, etc , the paraffin-embedded material was cut at 7 5µ and sections taken through the belly of this muscle were stained with Mallory triple stain The outlines of the fibres were drawn on squared graph paper with the aid of a camera lucida The average cross-sectional area and the standard error were determined in each case from a sample of 25 figures taken at random In the case of fibre measurements of the living muscle, the fibres were teased out in Locke's mammalian Ringer solution, and their diameters were measured immediately As the fibres were seen to be circular in transverse section, their cross-sectional area was obtained by treating them as cylinders Direct cross-sectional area measurements were found to be impracticable because the living material tended to contract on cutting The standard error of the living fibre sample was 106 sq µ The results are represented in the histogram (Fig 1)

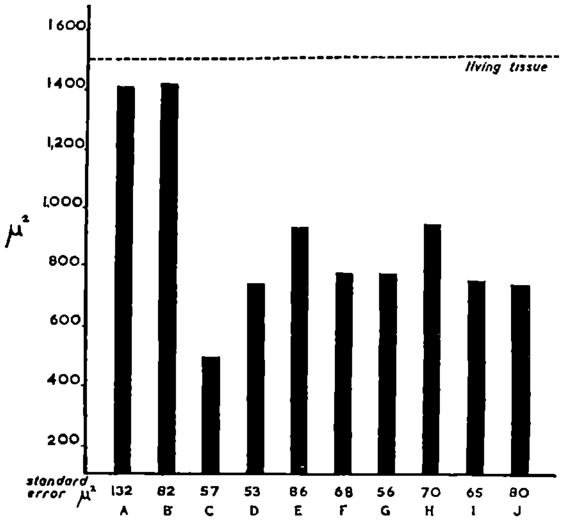

Fig 1 Effect of various fixatives on fibre cross-sectional area (fixation time in parentheses)
A, Champy's fluid (42 hr)
B, Flemming without acetic acid (42 hr)
C, Formol calcium (12 hr)
D, Bouin's (12 hr)
E Carnoy (3 hr)
F, Dalton's (1 hr and postchrome for 6 hr)
G, Neutral formalin, neutralized with sodium hydroxide (48 hr)
H, 2 per cent osmium tetroxide in acetone } freeze substitutions (1 week)
I, Carnoy
J, Methanol

The results of the freeze substitution technique[1] were surprisingly poor, these were repeated but the same extent of distortion occurred Sections of kidney prepared at the same time and in the same way showed no distortion In the case of muscle treated by the methanol freeze substitution technique, extensive breakage of the sarcolemma was noted Champy's fluid and Flemming's without acetic acid are seen to cause little shrinkage, and the results obtained from these two osmium tetroxide fixatives are very close to those for the living tissue, the histological appearance of such sections is extremely good and the muscle spindles are very well preserved It is often not practicable to use osmium tetroxide on a large scale, as it is relatively expensive and has only very low powers of penetration, thus limiting severely the size of the tissue which can be fixed It would seem that a slight shrinkage is inevitable, as the fibres will lose their turgidity on fixation

The other fixatives caused great distortion This could be readily seen because of the polygonal shape of fibres in transverse sections as compared with the spherical or ovoid shape of those fixed in Flemming without acetic acid, Champy's fluid, and the living fibres This distortion is probably due to a chemo-shortening of the fibrous connective tissue around the bundles

In the light of these results, it seems most unfortunate that much of the work on the shape and size of muscle fibre has been carried out on material fixed in formalin

RADIOBIOLOGY

Detecting Reversion in T4rII Bacteriophage to r^+ induced by Ultra-Violet Irradiation

DURING investigations into the mechanism of ultra-violet mutagenesis in extracellular phage, the following test was developed for estimating the extent of reversion of bacteriophage *T4B* from *r*II to r^+ induced by ultra-violet irradiation.

All *T4r*II mutants were obtained in this laboratory by ultra-violet irradiation of $T4Br^+$ phage 12 hr cultures of *Escherichia coli B* and *K*–12 (λ), obtained in 1958 from E Freese, were used in assays of *r*II and r^+ phage respectively Agar media were those of Chase and Doerman[1], broth media contained, per litre ion-free water, 10 gm tryptone, 8 gm sodium chloride, and 1 gm glucose Phage were diluted and irradiated in this broth All assays were performed by the agar layer method of Adams[2] To detect as few as 20–30 r^+ phage among 5×10^8 *r*II phage the concentration of bacterium *K*–12 (λ) per soft agar tube approached 2×10^9

A 15-watt 'Sylvania' 17-in low-pressure germicidal lamp was used to irradiate all samples at a distance of 67 cm. and at 4° C Phage samples were distributed as two-drop aliquots on glazed white porcelain spot test plates which were agitated during exposure Irradiated phage were handled in dim light to avoid photoreactivation Under these conditions a standard inactivation curve, graphed as the logarithm of percentage survivors against ultra-violet dose, was linear to 0 001 per cent survivors, 55 sec of ultra-violet irradiation resulted in a survival-level of e^{-1}

Each of 12 *r*II mutant stocks was assayed on *B* and on *K*–12 (λ) to determine accurately the titre of total and of r^+ phage Triplicate samples of each phage stock were irradiated to various survival-levels as indicated in Table 1 Two to three aliquots of these samples were then assayed on bacterium *K*–12 (λ) to obtain the titre of r^+ phage (background plus ultra-violet-induced mutants) Remaining aliquots of these samples were assayed on bacterium *B* to provide the exact survival-level

Results are presented in Table 1 Clearly 5 of the 12 mutants revert to r^+ when irradiated with ultra-violet The extent of reversion ranges from 1 81 $r^+/10^6$ survivors to $4 2 \times 10^5$ $r^+/10^6$ survivors Two other mutants (*UF*54 and *UF*147) may be weakly revertible but cannot be definitely classed as such since the proportion of r^+ phage per 10^6 surviving phage is so low as to make an accurate assay of their number unfeasible by this technique

Control experiments by Krieg[3] ruled out the possibility that the observed increase in r^+ phage might be due to ultra-violet-induced selection for r^+ phage present in the stocks before irradiation

This technique for detecting reversion differs from Krieg's[3] in the following points (1) Ultra-violet-irradiated phage are directly assayed for their r^+ content with no intervening cycle of phage growth (2) Our average number of lethal hits per phage was considerably lower than Krieg's[3], yet reversion was still demonstrable (3) Our multiplicities of infection of bacterium *K*–12 (λ) with ultra-violet-irradiated phage during r^+ assay were of necessity less than 1 Krieg's[3] multiplicities of bacterium *B* during the first cycle of ultra-violet-irradiated phage growth were considerably greater than 1, and lead to multiplicity reactivation The results presented here lead one to surmise that multiplicity reactivation is not a prerequisite occurrence for the ultra-violet-induced reversion of *r*II to r^+ phage

Table 1 EXTENT OF REVERSION OF *T4r*II TO r^+ INDUCED BY ULTRA-VIOLET RADIATION

Mutant	*n* where $e^{-n} = S/S_0$	Stock titre $\times 10^9$	r^+_s	r^+_s (S/S_0)	Total r^+ after ultra-violet irradiation	r^+ ultra-violet per 10^6 *S*	Reversion group

n, Average number of ultra-violet 'hits' per phage where $e^{-n} = S/S_0$ S/S_0, percentage of survivors, r^+_s, titre of r^+ phage present per ml, phage stock before irradiation, r^+, ultra-violet, total r^+ after ultra-violet $- r^+ (S/S_0)$ Reversion group *NR*, non-reverter, *R*, reverter *s*, strong, *w*, weak

The possibility is not ruled out that, when present, multiplicity reactivation may of itself lead to the production of revertants

Different *r*II mutants appear by this simple test to differ appreciably in their ability to be induced to revert by ultra-violet-irradiation Among the 5 *r*II mutants which could be induced to revert, the extent of reversion ranged from 1 81 to $4 2 \times 10^5$ r^+ per 10^6 surviving phage It is interesting that all those mutants which are most easily reverted by ultra-violet irradiation are also high-frequency spontaneous reverters The compartmentalization of this small sample into ultra-violet-revertible and ultra-violet-non-revertible is suggestive of some specific mutagenic effect of ultra-violet light upon free phage Investigations concerning this specific ultra-violet mutagenic effect on free phage, from r^+ to *r*II and from *r*II to r^+, will be published elsewhere

Effect of X-Irradiation on Self-Stimulation of the Brain

RECENTLY it has been shown that the brain is sensitive to low doses of ionizing radiation[1,2]. Prolonged exposure to X-irradiation decreases lever-pressing by rats[3]. Conditional aversion to saccharin results from exposure of rats to γ-radiation[4,5]. Because radiation affects psychological tests based upon food or fluid intake, we studied the effects of X-irradiation on rats trained to press a lever for electrical stimulation of the brain[6]. A single electrode was permanently implanted in the posterior hypothalamus of 8 *CFN* rats. After a training period of 6 months, the rats received 600 r. acute whole-body X-irradiation. Radiation characteristics were 250 kVp., 15 m.amp., focus-object distance 70 cm., filters, 0·21 mm. copper inherent, 0·5 mm. copper parabolic and 1·0 mm. aluminium, half-value layer 1·92 mm. copper; 22·9 r./min. measured in air.

Calibration of the machine was done with a Victoreen thimble r.-meter and output during irradiation was measured with a Radocon unit. On completion of the experiment, histological sections of the brain were compared with the de Groot atlas[7] to locate the electrode tip.

The responses of the animals can be divided into two groups. Those with high pre-irradiation rates (Fig. 1) had highly significant increases in the rate of lever-pressing on the day of irradiation. This was followed by return to, and a fluctuation within, the control values until the 17–19 post-irradiation day when there was a significant decrease in the rate of lever-pressing.

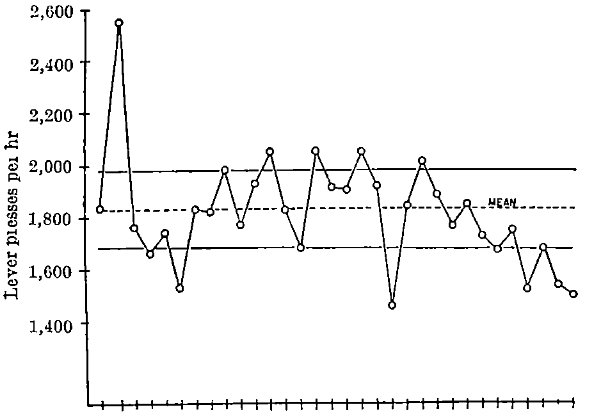

Fig. 1. Response of high-rate lever-pressing rat to 600 r. acute whole-body X-irradiation. The horizontal lines indicate the mean and standard deviation determined over a period of 6 months. The elevation of lever-pressing activity is highly significant ($P > 0{\cdot}001$). *C*, Control; *R*, irradiation day

The other group of 3 animals had low pre-irradiation rates (Fig. 2) and showed highly significant decreases in rate on the first post-irradiation day. These animals had difficulty in again attaining their pre-irradiation rates throughout the 30-day period of observation. Histological examination of the brains revealed that the rate of lever-pressing was not associated with any specific nucleus in the hypothalamus, because both high and low rates were obtained from nucleus arcuatus hypothalamic, nucleus dorsomedialis hypothalamic and area lateralis hypothalamic.

Although the usual transient loss in weight produced by the irradiation was seen, this effect apparently had nothing to do with the changes in performance of both groups of animals because they showed slight increases in weight during the 30-day observation period. These results indicate that self-stimulation of specific nuclei in the posterior hypothalamus may give high or low rates of response depending on the particular nucleus stimulated.

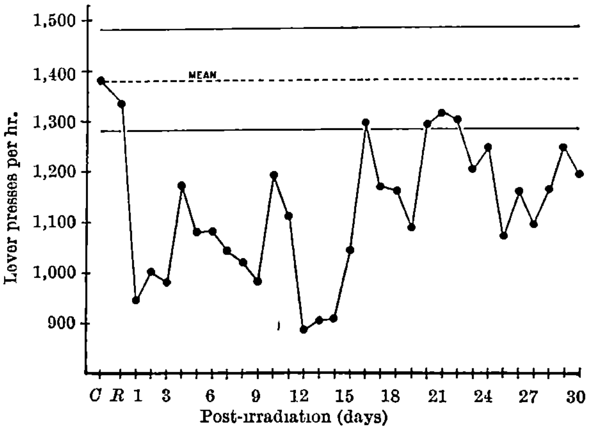

Fig. 2. Response of low-rate lever-pressing rat to 600 r. acute whole-body X-irradiation. The horizontal lines indicate the mean and standard deviation determined over a period of 6 months. The depression of lever-pressing activity is highly significant ($P = 0{\cdot}01$). *C*, Control; *R*, irradiation day

This confirms the observations of Hess[8] on the autonomic and somatomotor responses in the diencephalon, those of Gellhorn[9] on the autonomic areas and also those of Slusher and Hyde[10] on diencephalic control release of adrenocorticotrophic hormone. In all these cases, diametrically opposite actions were obtained by stimulation of similar areas. The depression of lever-pressing activity is much more prolonged than the stimulation of such activity. Thus, it would appear that the nuclei involved in these opposite actions may be directly affected by radiation, although the present experiments do not rule out the possibility that indirect and/or humoral agents from other areas in the body actually produced the effects observed. The question of direct versus indirect effects of the irradiation on the brain as well as the use of other electrode arrangements is now under investigation.

We wish to thank Dr. M. A. Slusher for her assistance. This work was supported by contract *AT* (04-1) *GEN*-12 between the Atomic Energy Commission and the University of California.

Concentration of Inhaled Cerium-144 in Pulmonary Lymph Nodes of Human Beings

In the course of an investigation of fission products deposited in human lungs[1], we have also measured the radioactivity of pulmonary lymph nodes. In most cases investigated so far, the amounts of fission products found were too small to permit deductions about concentration of these substances in the lymph nodes However, in some cases larger activities were observed and the occurrence of a concentration process could be clearly recognized

Concentration of radioelements in lymph nodes may, in certain circumstances, produce high local radiation dosages In evaluating radiation hazards due to inhaled radioelements it is therefore necessary to find out whether lymph nodes have to be considered as a 'critical organ' Many factors must be taken into consideration in this connexion[2,3], but the data required for this are only partly available so far Data about the concentration of inhaled radioelements in lymph nodes of human beings have been reported only in one case, that of a man who had occupationally inhaled plutonium-containing aerosols for several years[5] Further data on concentration in lymph nodes have been obtained in experiments with animals, chiefly with plutonium and polonium[2,3,5,6]

We wish to report three cases, in which our measurements give information about concentration of cerium-144 in human lymph nodes (Table 1). The lungs investigated were obtained from deceased persons, who had—like all people—inhaled the radioactive aerosol produced in nuclear test explosions in recent years The major part of the cerium-144 detected in our measurements on lungs was probably produced in the high-yield test explosions carried out in 1957 and 1958 Cerium-144 is particularly suited for studying the behaviour of inhaled 'fall-out'-particles for the following reasons (1) This fission product is present in fall-out largely in insoluble form[7] (2) Because of its half-life (285 days) and fission yield, cerium-144 is present in larger activity than other fission products in the period of approximately 1–4 years after formation by nuclear fission (ref 8)

The organs investigated came from older persons (58–81 years), who had lived in Vienna for at least several years and died here After the routine autopsy pulmonary lymph nodes (Lymphonodi bronchopulmonales, bifurcationis, tracheobronchiales, paratracheales) were removed This was facilitated by their dark coloration due to deposited anthracotic pigment, which is commonly present in city inhabitants Lymph nodes and lungs were then ashed separately In the ashes cerium-144 ($E\gamma$ = 134 keV) was determined by gamma-spectrometry using a well-type NaI(Tl)-crystal The spectrum was obtained in detail from 84 to 156 keV by measuring 32 min in each channel of 8-keV width In the cases reported here, the photo-peak at 134 keV was clearly identified We determined the area of the photo-peak above a 'background continuum', due in large part to the Compton continua of other radioelements and environmental radiation, and then calculated the amount of cerium-144 present by comparing with samples of known activity

In the first group of samples listed in Table 1, the lymph nodes from three lungs were combined in order to increase the activity to be measured Thus the concentration ratio observed for this group of samples represents a mean value for three individuals In the two other groups listed, activities of lung and lymph nodes of one individual were compared As shown in the last column but one, the cerium-144 activities found in the lymph nodes were between 1/8 and 1/3 of the activities of the lungs Since the mass of the lymph nodes is quite small, the specific activity (concentration of radioelement) in these organs is many times greater than in the remainder of the lung The concentration ratios calculated are given in the last column Because of the statistical error of the measurements, the values are only approximate, but it is apparent that an increase in specific activity of one to two orders of magnitude has occurred Rather similar values were found in the investigations cited above[3–6].

Pituitary Effect on Synthesis of Deoxyribonucleic Acid in Regenerating Rat Liver following Whole-body X-irradiation

WHOLE-BODY X-irradiation delivered within 6 hr of hepatectomy will inhibit the synthesis of deoxyribonucleic acid (DNA) in regenerating liver. This inhibition has been elegantly demonstrated to be a result of the failure to synthesize certain enzymes concerned with the formation of DNA[1] The nature of this inhibition of enzyme formation is suggested by two recent reports Myers[2] has reported that synthesis of DNA in regenerating liver is not completely inhibited following X-irradiation of liver only, and Benjamin and Yost[3] have observed that the uncoupling of oxidative phosphorylation seen in liver mitochondria following whole-body irradiation is due to a pituitary stimulation with subsequent activation of the adrenal cortical hormones These observations suggest that this interesting and rather unusual effect of low doses of whole-body X-irradiation on synthesis of DNA in the intact animal may be due to a pituitary stimulation which ultimately results in a decreased amount of energy being available for enzyme synthesis The possibility of a pituitary effect on synthesis of DNA in regenerating liver following whole-body X-irradiation was confirmed in the experiments reported here

Male Sprague–Dawley rats (180–200 gm) underwent partial hepatectomy by a standard method[4], and then were irradiated within 2 hr of the operation The animals were given 15 μc radioactive phosphate intraperitoneally 3 hr before they were killed (see Table 1 for schedule). Following killing, the livers of all animals within a group (2–3) were pooled, the DNA isolated, and the specific activity determined as suggested by Hecht and Potter[5] All irradiated animals received 750 r delivered by a General Electric 'Maxitron 250' operated at 30 m amp , 250 kVp with added filtration of 1 mm aluminium, 0·5 mm copper, delivering 106 r /min at 50 cm Shielding of animals was accomplished in a restraining box covered with 1 5 cm lead located outside the radiation beam

The results of these experiments are summarized in Table 1

Table 1 SPECIFIC ACTIVITY OF DNA ISOLATED FROM REGENERATING RAT LIVER FOLLOWING VARIOUS RADIATION PROCEDURES

Procedures	Time after death (hr.)	Specific activity (c p m /mgm)
Non-irradiated	18	0
Non-irradiated	22	777
Whole-body	22	0
Head only	22	0
Body only	22	38
Body only + 10 units of adrenocorticotrophic hormone	22	0
Body only + 1 unit of thyroid stimulating hormone	22	0

These experiments show that under conditions in which synthesis of DNA is active (19 hr postoperative), 750 r delivered either to the whole body or to the head will suppress synthesis of DNA in regenerating liver Head shielding resulted in a markedly reduced synthesis and the administration of pituitary hormones immediately following irradiation further abolished DNA synthesis The reciprocal experiments were also tried using commercial hypophysectomized rats but none of these animals survived the course of the experiment The conclusion from this series of experiments is that irradiation of the head alone produced the same inhibition of DNA synthesis in regenerating liver as irradiation of the whole body, and that DNA synthesis, although reduced, was present when the head was shielded The reduction of DNA synthesis in animals with their heads shielded may be the result of adrenal stimulation following X-irradiation

In view of the importance of regenerating liver as a system for studying synchronous formation of DNA, these experiments serve as a reminder that contributions from other organs in modifying synthesis of DNA in liver should not be ignored This is especially true in radiation work on synthesis of DNA as well as on population changes in 'radiation-sensitive' tissues

Radioprotective Effects of Reserpine and its *N*-oxide

CERTAIN amine oxides exert a protective effect against radiation injury[1,2] Reserpine has also been shown to have this action[3] This suggested a comparison between reserpine and its *N*-oxide Groups of 20 *CF*–1 mice were administered various doses of the two compounds 24 hr before X-irradiation with 600 r (Table 1) Radiation conditions were the same as described previously[1] Both compounds produced typical reserpine effects, sedation and ptosis, but the *N*-oxide was less active per dose All three doses of reserpine *N*-oxide significantly increased the ST_{50} day, whereas only one dose of reserpine had this effect (Table 1) On the basis of total survival it requires twice as much reserpine as its *N*-oxide to decrease mortality by 25 per cent, and neither compound is as effective as quinoxaline di-*N*-oxide[1] or anhydroerythromycin *N*-oxide[2] Mechanisms of action are probably different, since the reserpine compounds exert no antibiotic effects However, they have the proper chemical structures postulated for removing oxidizing radicals[2] Protection might be partially the result of the release of known protective compounds, adrenaline and 5-hydroxytryptamine[5] The release of catecholamines and 5-hydroxytryptamine is essentially complete 16 hr after reserpine administration, and the binding sites, as well as the plasma content, do not begin to contain appreciable amounts of these amines for at least 4 days[6–9] Metabolism and excretion are also going on at this time, and in all probability the amount of such amines available for exerting a protective effect is below that necessary for such an action On the other hand, reserpine has been found in body tissues for at least 48 hr following a single dose[10]. Most of the reserpine was found in the tissue cells where, in the present radiation experiment, it could act as a protecting compound The fact that reserpine and its *N*-oxide exert only a slight protective effect against

Table 1 ORALLY ADMINISTERED RESERPINE AND ITS *N*-OXIDE AND SURVIVAL AFTER X-IRRADIATION

BIOLOGY

Requirement of Essential Fatty Acids and Avian Atherosclerosis

ALTHOUGH Reiser in 1950[1] claimed that chickens needed a source of essential fatty acids during growth, the same author later concluded[2] that mature hens, maintained for a full year on a fat-free diet, did not require essential fatty acids for egg production or hatchability More recently Bieri *et al* [3,4] showed that chicks could be grown to maturity on an essentially fat-free ration without marked deficiency symptoms and suggested that Reiser's purified chick ration may have been deficient in thiamine and vitamin A In contrast with the chicken, exclusion of essential fatty acids from the diet of several mammals leads to a clear deficiency disease which, among more apparent external symptoms, is also characterized by an increase in liver and epidermal cholesterol and a decrease in serum cholesterol in the rat[5], and by aortic lesions in the pig[6]. Such observations lend support to the view of a possible connexion between deficiency of essential fatty acid and atherosclerosis[7] Since atherosclerosis develops in the chicken on low-fat as well as on normal rations[8], it seemed of interest to determine if rigid exclusion of essential fatty acid from the diet would aggravate aortic lesions At the same time more information regarding the requirement of essential fatty acids and deficiency symptoms would be obtained from a group of birds maintained continuously on a diet deficient in essential fatty acids from the day of hatching until 19 months of age

Day-old female chicks (10 per lot) were given either fat-free (albumen-glucose) or normal, fat-containing (about 3 per cent corn oil) rations for 19 months. On the fat-free diets the birds developed less rapidly (Table 1) than on the normal ration, but were otherwise asymptomatic. The early weight differences were largely overcome after 18 months. In our opinion the extreme dryness of the fat-free ration interfered with prehension and deglutition in the birds consuming this diet In order to improve the physical texture of the fat-free diet, starch was substituted for part of the glucose Although this improved the texture and increased feed consumption, it was found by analysis[9] that the starch supplied 0 06 per cent dienoic acid to the ration so that the starch was again removed Acid hydrolysis was used to determine any residual fat since conventional solvent extraction procedures were ineffective

Table 1 EFFECT OF THE EXCLUSION OF ESSENTIAL FATTY ACIDS FROM THE DIET OF CHICKENS

	Diet free of essential fatty acids	Normal diet containing essential fatty acids
Body-weight (gm)		
8 weeks	367 ± 16	695 ± 26
12 months	1,550 ± 74	1,773 ± 91
18 months	1,678 ± 53	1,735 ± 108

Pentaenoic	0	0 5
Hexaenoic	0	0 9
Plasma cholesterol (mgm /100 ml)	248 ± 23	160 ± 12
Atherosclerosis		
Aorta score †	1 7 ± 0 2	2 1 ± 0 2

* From eggs collected after one full year of production.

† Of the 10 chicks started on each diet there ultimately were 5 and 8 left at the end of 19 months on the fat-free and normal diets respectively Only non-specific causes were responsible for the deaths. For details regarding the scoring technique, see Fisher *et al* (ref 11)

The time of onset of egg production was delayed by one month in the birds on the fat-free diet, as shown in Table 1 Egg production was good, but sporadic, on the fat-free diet, and there was only one bird on this régime that never laid On autopsy, however, this bird was found to have been an internal layer with an active ovary at time of killing Egg production on the conventional ration was somewhat better It is also worth noting that fertilized eggs from the hens on the fat-free ration hatched apparently healthy chicks

Even after one year of egg production the eggs from the birds on the fat-free diet still contained small amounts of dienoic acid, as shown in Table 1 Even when the trace of dienoic acid (supplied by the starch which had been fed for a short time) is taken into account we cannot explain the origin of the dienoic acid in the eggs other than to suggest biosynthesis However, Murty *et al* recently showed that linoleic acid could not be synthesized from acetate by the laying hen[8] Compared with the eggs from birds on the normal ration, the trienoic acid content of eggs from birds maintained on a fat-free diet is almost 3 times as high Such elevated levels of trienoic acid in the tissue lipids have been considered an excellent indicator of the state of deficiency of essential fatty acids in the rat[10]

The plasma cholesterol values of the hens shown in Table 1 indicate a clear elevation in the fat-free versus the normal hens. By contrast, and in agreement with the observation of Horlick *et al.*[8], on a low-fat diet the visual aortic scores were actually lower in the fat-free, compared with the normal birds (Table 1).

In summary, it appears that in the chicken the exclusion of essential fatty acids from the diet does not aggravate atherogenesis even though the level of cholesterol in the blood is elevated. Moreover, no overt deficiency symptoms such as skin lesions or impaired reproductive functions were encountered.

Anthropometric Correlations between Adult Brothers

ANTHROPOMETRIC measurements have been made on 32 pairs of brothers. All subjects are adult men. The average age of the younger brothers is 32·3 yr., that of older brothers, 39·4. Age differences between members of the same pair vary from 1 to 20 years. The brother–brother correlations are shown in Table 1. Some coefficients are low but, unless below 0·35, they are significant at the 5–1 per cent level. Low coefficients are to be expected because in a panmictic population a brother–brother correlation should not significantly exceed 0·50 (or 0·42 for autosomal dominant characters). Other coefficients are higher but, as for low significant correlations, with two exceptions there is no significant departure from 0·50. For head breadth and cephalic index, correlations are surprisingly high and significantly above 0·50. Such values can be expected if, instead of random mating, there is a fairly high degree of homogamy. In man, assortative mating exists primarily for body-height, secondarily for some characters correlated with stature. In our sample, fraternal correlation for body-height is low and does not differ significantly from 0·50, the limiting value compatible with panmixia. One can guess that assortative mating is directly related to some other anatomical traits, but it is hard to believe that cephalic index, which gives the strongest correlation, can be sexually attractive. A quite different explanation seems to be more credible.

* Corrected figures published by J. M. Tanner (ref. 1).

Our sample does not represent a definite geographical area. As for many other samples, it is fortuitously mixed, because subjects come from different parts of the country. Two groups of fraternal pairs come from two distinct areas, the populations of which are anthropologically different. One is far more dolichocephalic than the other. In our small sample, these two groups are strong enough to increase the coefficient of correlation. The mingling of two more or less dissimilar groups—panmictic but 'allopatric'—can exaggerate fraternal correlations in a way which simulates homogamy. After all, in this case, excessively high correlations are due to a kind of assortative mating, not by choice, but by geographical isolation. Therefore, both exceptionally high fraternal correlations are not intrinsically wrong, but their numerical value should be reduced in some way.

On the whole, significant correlations are in accordance with other data. Unfortunately, so far as I know, only three series of fraternal correlations have been published, with not entirely comparable assortments of characters[1]. Seven correlations of Table 1, without corresponding values in Howells's data, have been calculated probably for the first time. In 22 pairs, the eye colour, classified as light (blue, grey) and dark (all other shades), is similar ($\chi^2_1 = 4{\cdot}57$; $P = < 0{\cdot}05$). But for hair colour there is no fraternal similarity.

Goblet Cells in the Swim Bladder of *Ophiocephalus striatus* (Bloch)

DURING investigations on the mechanism of gas secretion by the gas gland epithelium in the swim bladder of teleosts, a preliminary investigation was made of the histology and histochemistry of the gas gland to identify the types of cells which are involved in the secretion of gases.

Adult *Ophiocephalus striatus* were caught as and when required and stunned by a blow on the head and the swim bladder rapidly dissected out and fixed in Zenker's, Helly's and Champy's fluids, a saturated solution of mercuric chloride in 70 per cent alcohol with 2·5 per cent potassium dichromate, a mixture of equal parts of saturated aqueous mercuric chloride and 2·5 per cent aqueous potassium dichromate, and a solution of equal volumes of 8 per cent aqueous basic

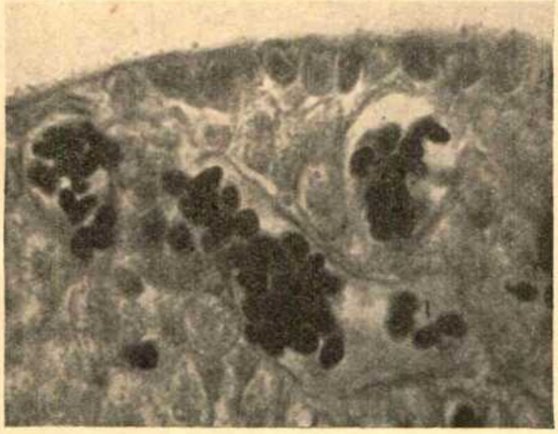

Fig. 1. Swim bladder epithelium of *Ophiocephalus striatus* (× *c.* 970). Fixed in saturated mercuric chloride with 2·5 per cent potassium dichromate and stained with Bensley's neutral gentian. Note along the border of the epithelium rounded, deeply stained cells with thick striations in the cytoplasm. The very dark bodies are blood cells

lead acetate and 16 per cent formalin. They were washed, dehydrated and embedded in paraffin as usual. Sections 2–6μ thick were stained with hæmatoxylin-eosin, Mann's stain, rapid phloxine-methylene blue, Bensley's neutral gentian and Delafield's hæmatoxylin.

These stains revealed a type of cell which is different from the main types of cells found in the swim bladder epithelium. This type of cell is found only towards the lumen of the bladder and is seen distinctly as a one-cell border in places where the cells are present in large numbers (Fig. 1). They are not seen in the depths of the glandular mass. In the region of the main glandular mass these cells are relatively less numerous but more abundant where the epithelium is thin.

The cells are usually rounded or ovoid and similar to goblet cells seen elsewhere. The nucleus is seen pushed to the base of the cell away from the lumen. In all the stains used the nucleus has taken a blue colour. Clear cytoplasm is seen just around the nucleus and above this is the condensed matter with very fine granules filling almost the entire cell. In some cells the condensed matter appeared to be crescentic. The space around these cells is clear of stain. In the rapid-phloxine methylene-blue stain the cytoplasm of the cell is stained a bright pink. In sections stained with Mann's stain these cells have taken less eosin than the main glandular mass adjacent to them. The condensed matter is stained violet with Bensley's neutral gentian, and often a clear border is present between the condensed matter and the cell wall. In some cells, probably spent ones, there can be seen violet round bodies, while in many others violet striations along the long axis are seen in addition. In the slides stained with hæmatoxylin-eosin, only a slight difference is seen in the staining between these cells and the rest of the gland cells.

These cells resemble the goblet cells seen in the epithelial lining of the intestines. Hence some sections were stained in 0·1 per cent toluidine blue in 1 per cent alcohol and others in 0·1 per cent toluidine blue in 30 per cent alcohol and some others in 0·2 per cent Ehrlich thionin for mucoproteins. There was no metachromasia in the cells of the swim bladder epithelium while there was well-marked metachromatic staining of the intestinal goblet cells which was more pronounced with the dye made in 30 per cent alcohol and still better in the thionin. Cells similar to those observed have not been described by previous workers on the fish swim bladder. George[1], who has studied the swim bladder epithelium of four species of *Ophiocephalus*, fails to mention their occurrence. Such cells have, however, been described in the alimentary tract of *Labeo* by Girgis[2] and in the epithelium of the accessory respiratory organs of *Clarias*, including the air chamber, by Moussa[3]. Their function is that of secreting mucin, and so it seems quite likely that the cells seen in the swim bladder also have a mucus-secreting function. It is evident, however, that there is some qualitative difference in the products of secretion produced by the cells described here and those occurring in the intestinal mucosa.

In the swim bladder of *Gadus morhua* "a copius secretion of a viscid, slimy opaque material" has been described by Vincents and Barnes[4]. Fange[5] worked on this material and he says "that very probably the secretory product discovered by Vincents and Barnes in some way originates from vacuoles of the gas gland cells". He has not, however, identified any particular type of cell causing this secretion. The presence of a slimy secretion in the lumen of the swim bladder has been reported by many other workers also. Scholander[6] notes that the bubbles of gas are secreted into the mucus covering the gland. The mucus may, therefore, have a very important function with reference to gas secretion. It is also quite likely that there has been some confusion in the material examined by these workers as they think that these secretions are in the nature of myelin and related to the secretory vacuoles. Vacuoles and granules have also been observed in the gas gland of this fish in the cytoplasm of the main type of cells; but no vacuoles have been seen in the cells described here. The vacuoles of the gland cells are probably related to the gas-secreting activity of the gland. Thus the cells described here seem to be different in function and to be responsible for a mucoid secretion. Further work is progressing under the supervision of Prof. C. M. Francis, of this College.

Natural Occurrence of *Leptospira icterohæmorrhagiæ* in the Eastern Grey Fox and the Eastern Raccoon

PREVIOUS investigations of wild life in the United States have established the grey fox and the raccoon as natural hosts of leptospires. *Leptospira ballum*[1], *L. australis A*[2], and *L grippotyphosa*[2] have been isolated from the grey fox. *Leptospira ballum*[1], *L. pomona*[1], *L. australis A*[3], *L. grippotyphosa*[2], *L. autumnalis*[4], and *L. mini-Georgia*[5] have been isolated from the raccoon.

This communication concerns the first isolations in the United States of *L. icterohæmorrhagiæ* from the

Table 1. LEPTOSPIRAL ISOLATIONS FROM KIDNEY SUSPENSIONS

Animal	Day growth detected	Mediums supporting growth
Grey fox—38	Day 12 post-inoculated	Semi-solid Fletcher—horse; semi-solid Chang's—horse
Raccoon—7	Day 5 post-inoculated	Semi-solid Fletcher—horse
Raccoon—76	Day 12 post-inoculated	Semi-solid Chang's—horse and rabbit; 10^{-4} diluted semi-solid Fletcher—rabbit
Raccoon—80	Day 8 post-inoculated	Semi-solid Fletcher—horse; semi-solid Chang's—horse; 10^{-2} and 10^{-3} diluted semi-solid Fletcher—rabbit

eastern grey fox and the eastern raccoon. The isolations were made during the course of an epizootiological investigation of leptospirosis in Pennsylvania wild-life.

The species of wild-life investigated were caught in No. 2 coil spring steel traps. Specimens were removed alive from the traps and transported to the School of Veterinary Medicine, University of Pennsylvania. On arrival at the Laboratory, the animals were asphyxiated in a carbon monoxide chamber. Blood specimens for serological testing were collected and a portion of one kidney was removed aseptically from each animal.

Each kidney specimen was ground with sterile mortar and pestle and diluted to a 10 per cent suspension with Stuart's liquid medium base (Difco). One to three drops of the suspension were inoculated into one tube of each of the following media: Fletcher's semi-solid medium (Difco) with 10 per cent rabbit serum, Fletcher's semi-solid medium with 15 per cent horse serum, Chang's semi-solid medium with 15 per cent horse serum, and Stuart's semi-solid medium[7] with 10 per cent rabbit serum.

Serial ten-fold dilutions of the kidney suspension were made, with Stuart's liquid medium base, to approximately 10^{-1} to 10^{-5} final dilutions. One to two drops of each dilution were inoculated into a tube of Fletcher's semi-solid medium with 10 per cent rabbit serum. All inoculated mediums were incubated at 29° C. and examined by dark-field microscopy at 10–14-day intervals. Culture results are summarized in Table 1.

Sub-cultures of media containing growth of Leptospires were made into Fletcher's semi-solid medium with 10 per cent rabbit serum and Stuart's liquid medium with 10 per cent rabbit serum. Sub-cultures of each isolate were sent to the World Health Organization Reference Laboratory for Leptospirosis, Walter Reed Army Medical Center, Washington, D.C., and to the Leptospirosis Unit, Animal Disease Eradication Division, Ames, Iowa, where they were identified as *L. icterohæmorrhagiæ*.

Microscopic agglutination tests were conducted on serum specimens collected from each animal at the time of culturing using an antigen bank of eleven leptospiral serotypes: *L. bataviae*, *L. pomona*, *L. autumnalis*, *L. ballum*, *L. canicola*, *L. icterohæmorrhagiæ*, *L. alexi*, *L. grippotyphosa*, *L. australis A*, *L. sejroe* and *L. hyos*. Test results are summarized in Table 2.

Dr. Clark and Mr. Kresse are on assignment from Laboratory Services, Animal Disease Eradication Division, Agricultural Research Service, United States Department of Agriculture.

This work was supported in part by United States Public Health Service grant *E*-2821.

Synergid Haustoria of *Quinchamalium chilense* Lam.

DECAISNE[1] pointed out that in *Santalum album*, *Nanodea*, *Myoschilos*, *Osyris* and more obscurely in *Quinchamalium*, the tip of the embryo sac extends beyond the ovule into the ovarian cavity. The present account is based on an investigation of *Quinchamalium chilense*, a native of the South American Andes.

The ovary is inferior with a free-central placental column, bearing three hemianatropous, unitegmic ovules, the nucellus being reduced to one or two epidermal cells capping the megaspore mother cell. The thick integument does not grow beyond the nucellus and thus a micropyle is not formed. The embryo sac is of the Polygonum type and extends beyond the ovular epidermis at the 4-nucleate stage. At maturity it comprises the egg apparatus, two polar, and three antipodal nuclei. The latter are separated from the rest of the embryo sac by a wall, but do not become organized into individual cells.

In most of the Santalaceae, the synergids are inconspicuous, have small nuclei, and degenerate before or soon after fertilization. In *Q. chilense*, on the contrary, they are unusually large and pear-shaped with prominent nuclei. Even in unpollinated flowers they protrude beyond the embryo sac (Fig. 1*a*) and eventually extremely long (approximately 1,200μ) tubular structures reaching up to one-third the length of the style are formed (Fig. 1*b*). These are densely cytoplasmic and sometimes persist until the endosperm has become quite massive. Dahlgren[2] has recorded that in some members of the Compositae, namely, *Calendula arvensis*, *Mutisia candolleana* and *Ursinia anthemoides*, the tips of the synergids extend into the micropyle and even beyond it, sometimes reaching as far as the funiculus. Paliwal's[3] observation that in *Santalum album* dichotomously branched synergid haustoria develop after fertilization has been contradicted by Bhatnagar[4]. The

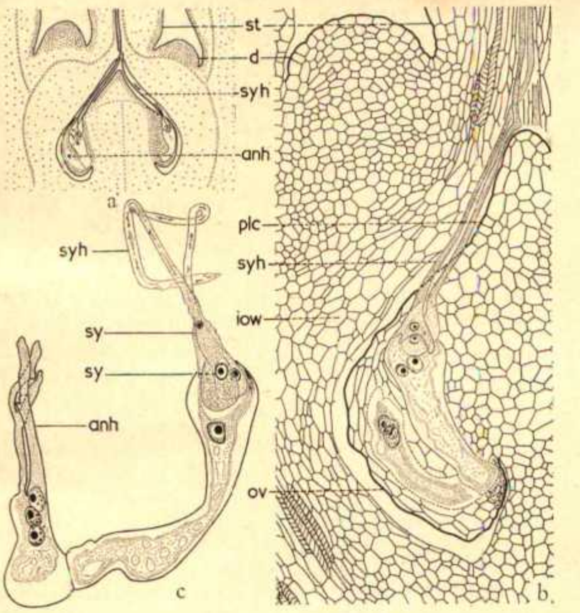

Fig. 1. *a*, Longisection of base of flower showing floral parts and extension of synergid and antipodal haustoria (× 40); *b*, semi-diagrammatic enlargement of 1*a* to show the details of embryo sac in relation to ovary and style (× 124); *c*, whole mount of embryo sac showing the synergid and antipodal haustoria (× 262). anh, Antipodal haustorium; d, disk; iow, inner ovary wall; ov, ovule; plc, placental column; st, style; sy, synergid; syh, synergid haustorium

latter author has pointed out that in this plant the synergids degenerate soon after fertilization and that Paliwal had mistaken the persistent pollen tubes which remain adhering to the embryo sac (see also Griffith[5,6]) for synergid haustoria. Thus, *Quinchamalium* has perhaps the longest synergid haustoria so far known in any angiosperm.

In addition to very long and conspicuous synergid haustoria *Quinchamalium chilense* also shows a much-branched antipodal haustorium. As mentioned earlier, the antipodal nuclei do not become organized into cells. Instead, they enlarge, become hypertrophied and multinucleolate and may even divide. Later the chalazal end of the embryo sac extends as far as the placental column and branches profusely (Fig. 1c). These branches ramify into the placental tissue in the vicinity of the vascular supply. In the Santalaceae an extension of the chalazal end of the embryo sac into a cæcum leaving the antipodal cells *in situ* is a common feature. In *Quinchamalium* the antipodal nuclei are carried at the tip of the haustorium until it branches (Fig. 1c). The activity of the synergid and antipodal haustoria declines with the progressive development of the endosperm.

The embryology of other species of *Quinchamalium* and allied genera, namely, *Arjona* and *Myoschilos*, is as yet unknown and it would be worth while to investigate them to ascertain if prominent synergid haustoria develop in these plants also.

I shall be grateful if botanists could help me in procuring the preserved materials of all stages of buds, flowers and fruits of different species of *Arjona* and *Myoschilos*.

I am indebted to Dr. B. M. Johri and Prof. P. Maheshwari for guidance. Thanks are also due to Dr. S. P. Bhatnagar for comments, to Mr. V. Garcia, University of Buenos Aires, Argentina, now working at the University of Delhi, for providing the material, and to the Council of Scientific and Industrial Research for financial assistance.

Relation between Organophosphorus-Resistance and Non-Diapause in Spider Mites

As has been shown by Lees[1], the females of *Tetranychus urticae* enter into diapause under the influence of a short-day treatment during their development. High temperatures tend to prevent diapause even if the photoperiod is short.

An investigation into the diapause-pattern of several spider mite populations originating from places in different countries (the Netherlands, Belgium and Germany) proved that the critical area of the diapause-pattern of seven populations was significantly smaller than may be expected. Only four populations showed a diapause-pattern in accordance with the data of Lees.

In work on the susceptibility of the populations to organophosphorus compounds it appeared that the seven populations with the deviating diapause-pattern were organophosphorus-resistant; the four

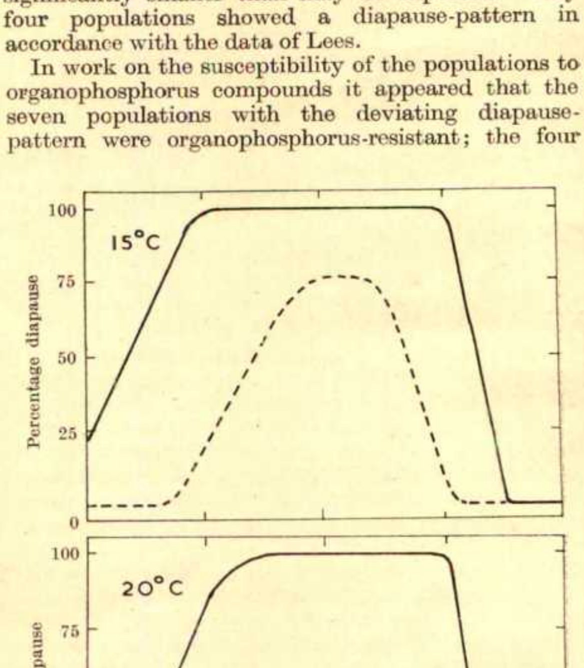

Fig. 1. The effect of photoperiod on the incidence of diapause in two populations of *Tetranychus urticae*. The dotted line represents an organophosphorus-resistant population, the continuous line a susceptible population

populations with a normal diapause-pattern showed a high susceptibility to organophosphorus compounds.

Fig. 1 shows the difference in diapause-pattern between a susceptible and an organophosphorus-resistant population. At 20° C. a régime of short photoperiods evoked only a small percentage of diapause forms in the resistant population. At 15° C. resistant mites entered into diapause, but the percentage of diapause forms was significantly lower with the resistant population than with the susceptible one.

Effect of Copper Deficiency in White Clover on Nitrogen Fixation

IN view of a recent report by Hallsworth *et al.*[1] that copper stimulates nitrogen fixation by subterranean clover (*Trifolium subterraneum*), the following evidence from a field trial is presented as indicating a similar function of copper in nitrogen fixation by white clover (*T. repens*).

White clover was dissected from mixed herbage samples taken on November 27, 1956, from a rates of copper trial conducted by one of us (F. H. v. d. E.) on a pasture recently established on raw peat on the Moanatuatua swamp. The samples were analysed for copper and total nitrogen contents.

Many clover plants in the control plots showed characteristic copper deficiency symptoms—die-back with bleaching of the margins and rolling and collapse of the leaflets. The samples analysed were apparently healthy whole leaves (leaflets plus petioles).

Table 1. YIELDS OF MIXED HERBAGE AND COPPER- AND NITROGEN-LEVELS IN WHITE CLOVER

Treatment		Dry matter yield (lb. per acre) (Spring 1956)	Copper (p.p.m. in dry matter)	Nitrogen (percentage in dry matter)
Control		2,090	2·5	4·25
5 lb. Bluestone		3,330	3·6	4·88
10 lb. Bluestone		3,410	4·0	4·94
20 lb. Bluestone		3,540	6·6	5·05
40 lb. Bluestone		3,520	7·2	5·00
80 lb. Bluestone		3,520	8·2	5·03
Significant	5%	350	0·78	0·16
differences	1%	470	1·05	0·21

The copper treatments resulted not only in increased growth of white clover and elimination of deficiency symptoms, but also in significantly higher concentrations of total nitrogen. Incubation tests of the peat soil with copper additions failed to demonstrate any increase in mineral nitrogen-levels. The clover nitrogen-levels in the controls were relatively low for succulent spring growth under local conditions, but normal in the copper-treated plants. The presence of copper deficiency symptoms together with low nitrogen- and very low copper-levels suggests that the increases in nitrogen concentrations in the clovers were due to a specific effect of copper on nitrogen fixation by white clover.

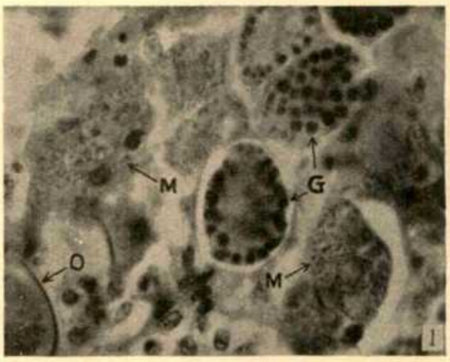
Limitations of the Periodic Acid–Schiff Technique for the Demonstration of Stages of *Eimeria* in Tissues

IN a recent communication, Jennings[1] suggested that the periodic acid–Schiff technique is useful for the demonstration of all stages in the life-cycles of four species of coccidia occurring in the intestine of the fowl. These species were *Eimeria acervulina*, *E. maxima*, *E. necatrix* and *E. tenella*.

The periodic acid–Schiff technique was first applied to *Eimeria* by Lillie[2], who obtained positive reactions in the cytoplasm of oocysts of *E. stiedae* from the rabbit. More recently, this technique was used by Cheissin[3] on *E. magna*, *E. media* and *E. intestinalis* from the rabbit, Pattillo and Becker[4] on *E. acervulina* and *E. brunetti* from fowls, Gill and Ray[5] and Tsumoda and Itikawa[6] on *E. tenella* from fowls. These authors all failed to obtain positive reactions by the periodic acid–Schiff technique with some stages of these life-cycles. Cheissin found that isolated microgametes were negative and that microgametocytes gave only an insignificant reaction. Pattillo and Becker obtained no positive reactions using the Hotchkiss[7] periodic acid–Schiff technique with the microgametocytes and schizonts of both *E. acervulina* and *E. brunetti*, although the merozoites of *E. acervulina* gave a weak reaction. Developing macrogametocytes were often negative.



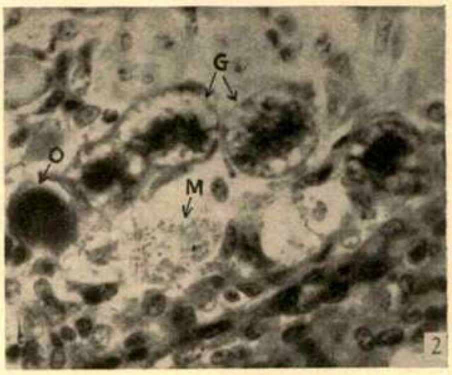


Fig. 1. Section of small intestine infected with *E. maxima* and fixed in formol saline; stained by Hotchkiss periodic acid–Schiff technique and counter-stained with hæmalum. Note the intense staining of the 'plastic granules' (*G*) in the macrogametes and oocyst wall (*O*). The microgametocytes and microgametes (*M*) have stained with the hæmalum but not with the periodic acid–Schiff reagent. (× 525)

Fig. 2. Section of small intestine infected with *E. maxima* and fixed with Bouin's fluid; stained by Hotchkiss periodic acid–Schiff technique and counter-stained with hæmalum. Note the lack of preservation of the plastic granules in the macrogametes (*G*); the microgametocytes and microgametes (*M*) have stained with the hæmalum, but not with the periodic acid–Schiff reagent. (× 525)

In our experience, the invading sporozoites and merozoites of *E. tenella* give only weak reactions and consequently the technique is of little value in demonstrating these stages in tissues. Long and Rootes[8], using the Hotchkiss periodic acid–Schiff technique, showed that the reactions of the prominent so-called 'plastic granules' of the macrogametes depend on the type of fixative used (see Figs. 1 and 2). According to Pattillo and Becker, these granules probably consist of a protein–carbohydrate complex, which is unaffected by pre-treatment with saliva or α-amylase. Fixation with Bouin's fluid fails to preserve these granules, and negative results are obtained with the periodic acid–Schiff technique although there is no interference with the staining of the glycogen in the cytoplasm. For these reasons the periodic acid–Schiff reaction is not an appropriate technique for the demonstration of all stages of the life-cycles of *Eimeria*, and when used on sections of very heavily parasitized intestinal tissue, large amounts of mucus giving a positive reaction with the periodic acid–Schiff technique may mask the parasites. The same difficulty may be encountered when the technique is applied to sections of rabbit liver containing trophozoites and small stages of the asexual and sexual cycles of *E. stiedae*, because of the possible masking effect of the stained liver glycogen.

CYTOLOGY

Identification of the Chromosome Complements of New-born and Adult Living Mice

Chromosome abnormalities similar to those known in man are now being found in mice[1]. Identification of the chromosome complement of these mice in cells from bone marrow[2] or corneal epithelium[3] involved the death of the animals. The advantage in identifying the chromosome complement of living mice is obvious, and the present communication describes techniques to achieve this in new-born and in adult mice, chiefly by the use of primary outgrowths of cells from pieces of tissue cultured *in vitro*.

The chromosome complement of new-born mice aged 1–3 days has been identified in cells from small pieces of tail. Loss of their tail-end does not obviously affect the development of these mice. Attempts to obtain cells in mitosis for chromosome counts directly from the tail-pieces were not uniformly successful, hence the pieces have been cultured *in vitro*. Before removal from the mouse, the tail-ends are washed in a mixture of alcohol and ether; this serves as a partial anæsthetic and to clean the tails. The excised tail-ends are then washed in Gey's solution containing mycostatin, penicillin and streptomycin, cut into four or five small pieces, and mounted separately in tiny plasma clots on a 3/4 in. cover-slip. The cover-slip is inverted in a cavity cell, and growth medium is added. Antibiotics and mycostatin are necessary to keep down bacteria and fungi respectively. Initially, Gey's solution containing 15 per cent calf serum, 2 per cent chick embryo extract, and 0·5 per cent lactalbumin hydrolysate was used as the growth medium, but this was later superseded by medium 199 (Glaxo Laboratories), plus 15 per cent calf serum. The medium is changed every other day, and all cavity cells are gassed with 5 per cent carbon dioxide.

Cells emerge from the grafts within one or two days (Fig. 1). After 4–5 days, the cell monolayer in many of the cultures is ready for cytological preparation. The small pieces of tail, still easily recognizable, are gently pulled off the cover-slip with least disturbance to the cell monolayer, and are re-embedded in tiny plasma clots on another cover-slip to serve as a reserve if needed. The cover-slip containing the cell monolayer is then re-inverted into the growth solution and treated for chromosome processing in a manner similar to that described in ref. 4: 'Colcemid' (Ciba Pharmaceuticals) at a concentration of 0·25–0·50 μgm./ml. for 2 hr., hypotonic saline for 15 min., and fixation in 45 per cent acetic acid. In practice, after removal of the growth medium 'Colcemid' mixture, 1 ml. saline is placed in the cavity cell, 2·5 ml. distilled water is added dropwise, and the acetic acid added slowly 15 min. later. This concentration of hypotonic saline, and the gradual addition of water and fixative, were found to give good spreading of the chromosomes with minimal cell breakage. After fixation, the cells were dried in air and stained by the Feulgen technique.

Mitoses are found in the great majority of the preparations. The clarity of many mitoses is sufficient to count the chromosomes easily (Fig. 2), and more than thirty of them can be selected in some cultures. If this number is not available, or if more are required, the reserve culture is available a few days later. The mitotic index is especially high in cultures fixed 10–11 hr. after change of growth medium. Details of the counts on mitoses in six tails are given in Table 1. Almost all were diploid; a few were found with less than the diploid number, and were presumably a result of cell breakage. The technique obviously

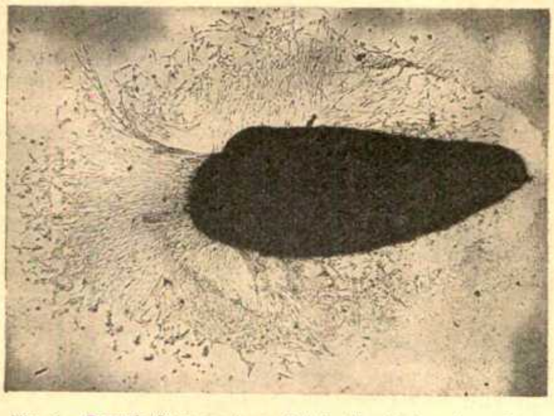

Fig. 1. Growth from a piece of tail after 3 days in culture. (× 22)

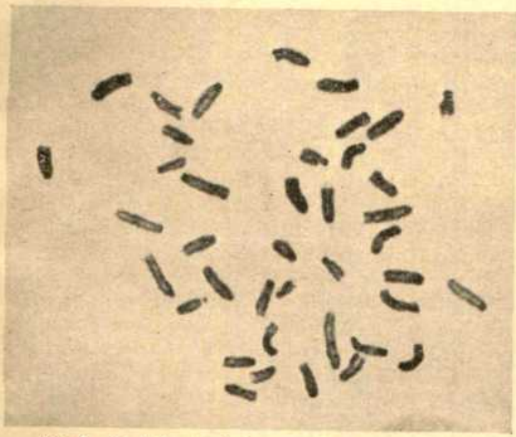

Fig. 2. Diploid mitosis from a tail culture. (× 756)

permits a fairly rapid identification of the chromosome complement of new-born mice, and twenty-two such mice have recently been examined here using an arbitrary limit of twelve clear mitoses for classification. Thirteen were classified within 5 days, six others within 7 days, and two more after 10 days; the last culture was lost through bacterial contamination.

Table 1. CHROMOSOME COUNTS ON CELLS IN OUTGROWTHS FROM TAIL-TIP AND EAR-CLIP CULTURES

Tissue	No. of mitoses examined	Chromosome counts 31	33	39	40
Tail	68	1		2	65
Ear	45		1	1	43

Table 2. GROWTH FROM EAR CULTURES

Ear tissue	Proportion of successful cultures after 12 days	Mean interval (days) until: First appearance of fibroblasts	Ready for processing
Normal	7/10	7·4 ± 0·3	14·5 ± 0·8
Regenerating for 2 days	13/13	3·6 ± 0·2	9·6 ± 0·6
Regenerating for 4 days	11/12	3·4 ± 0·3	10·2 ± 0·4

The chromosomes of adult mice were also counted in cells grown *in vitro*. Mitotic cells can be obtained directly from mice by partial splenectomy, but such an operation is often undesirable. Pieces of skin are not very suitable for obtaining cell outgrowths; growth is very slow or absent, and bacterial and fungal infections are frequent. Small pieces clipped from the ears produce a better growth. The most successful method is to make a small cut in the ear of the mouse and, 2 or 4 days later, remove small pieces containing the regenerating tissue. Cells now emigrate from the ear tissue much sooner (Table 2), and the cell monolayer can be processed for chromosome counts after approximately 10–15 days. Details of the counts made on four ear cultures are given in Table 2. The technique clearly serves to obtain an indication of the chromosome complement of the adult mouse with the minimum of discomfort to the animal.

GENETICS

A Heterocaryon possessing Haploid and Diploid Nuclei

IN general, a heterocaryon between a white and a yellow mutant of *Aspergillus* fungi gives rise to white, yellow, and green progeny. It was found recently, however, that five heterocaryons produced between two of the seven colour mutants of *A. sojae* strain *K* could give brown progeny besides the white, yellow, and green. Evidence that the brown strain appears to be a heterocaryon possessing haploid and diploid nuclei in a common cytoplasm is to be described.

Among the five heterocaryons, a heterocaryon between a white histidineless mutant and a yellow leucineless mutant was investigated extensively. The heterocaryon was produced by the method reported in ref. 1. When conidia of this heterocaryon were plated on minimal medium (Czapek agar), there appeared four kinds of colonies, namely, white 12, brown 6, green 10, and heterocaryotic colonies 4,410. Eight of the heterocaryotic colonies had brown sectors.

A conidial suspension prepared from a whole brown colony, in which more than 90 per cent of conidia were single, was spread on complete medium (Koji extract agar), and the conidial colour and nutritional requirement of each colony were examined after one week. In approximately one thousand colonies, 84 per cent were yellow, 13 per cent brown, and 3 per cent green. Using one of the brown colonies thus obtained, plating was done again on the complete medium. Results are shown in Table 1 together with the results of the third experiment. It is noteworthy that no white colony was found among the conidia of the brown strains. In addition, the yellow colonies were dependent on leucine and the brown and the green colonies were prototrophic. In contrast with this, for normal heterocaryons there was no green colony, so far as was tested, although they gave white, yellow, and heterocaryotic colonies (Table 1).

Table 1. PATTERN OF SEGREGATION OF THE BROWN STRAINS AND NORMAL HETEROCARYONS

	Brown strain					Normal heterocaryon				
	Segregation ratios (per cent)				No. of colonies examined	Segregation ratios (per cent)				No. of colonies examined
No. of transfer	*W*	*Y*	*B*	*G*		*W*	*Y*	*X*	*G*	
1	0	84	13	3	1,100	44	43	13	0	1,680
2	0	88	9	3	1,010	41	48	11	0	986
3	0	87	12	1	1,166	40	50	10	0	802

W, White histidineless; *Y*, yellow leucineless; *X*, heterocaryotic prototroph; *G*, green prototroph; and *B*, brown prototroph.

In order to estimate ploidy of the yellow and the green segregants, numbers of nuclei/conidium were examined by the method described in ref. 2. Results were that the yellow conidium contains on the average 3·5 nuclei and the green conidium 1·7. These values approximate to those in a haploid (3·5) and a heterozygous diploid conidium (1·6) which was produced by the authentic method[3,4]. Moreover, the yellow clone was stable, and the green clone gave white and yellow progeny after a long cultivation. The appearance of white progeny from the green strain might be due to either somatic recombination or reduction[5]. It is concluded, therefore, that the nuclei in yellow conidia are haploid and the nuclei in green conidia diploid.

It is known that a white haploid nucleus and a yellow haploid nucleus in a heterocaryotic cell can conjugate under natural conditions to form a heterozygous diploid nucleus which develops green colour. In the heterocaryon described before (the original heterocaryon), it seems that the diploid nuclei are seldom segregated and transmitted to progeny together with the yellow nuclei. The resulting progeny are brown. Because a single conidium of the brown strain gives rise to yellow and green progeny, the conidium is considered to be a heterocaryon possessing both haploid and diploid nuclei. The average number of nuclei in a brown conidium is about 3·0.

ANTHROPOLOGY

Possible Origin of the Use of Fire by Early Man

THOUGH many animals can become accustomed to the presence of fire, man alone has learned to produce, to maintain and to control it. However, this achievement is not peculiar to *Homo sapiens*. Fire was known also to *Homo neanderthalensis* and *Pithecanthropus pekinensis*[1]. From the study of fire-myths and the cultures of primitive races, it is usually presumed that fire was first obtained from such natural sources as volcanoes, bush fires, lightning, sparks struck from stones, or dry branches rubbing together in the wind[2–5]. Myths, however, are not necessarily reliable as guides to the distant past, while the reaction of animals, even of modern man, to volcanoes and forest fires is one of terror. Even when fear has been mastered, the practical difficulties of obtaining fire from these sources are still immense. Natural production of fire by friction or percussion is too rare to be readily observed by members of a small and scattered population.

An alternative to present theories is that use of fire itself is secondary to use of heat derived from bacterial decomposition of plant material. The heat produced by a haystack or compost heap is a matter of common knowledge. This heat may well become great enough to result in fire. Since many animals use as beds piled and trampled grasses, early man may well have slept in a similar manner. Individuals leading a purely nomadic existence would not use their bedding heaps sufficiently long for the warmth of decay to become apparent, but so soon as a more settled mode of life was adopted bacterial decay of the bedding could become important. Accumulation of sun-dried vegetation in a bed, perhaps a communal one, could lead to the 'compost heap' situation, presenting man with a small-scale source of heat. At first this would merely increase the temperature of his bed; later it might lead to the idea of the peat fire or even of earth-oven cooking. Occasionally, no doubt, such beds would burst into flame, providing at once the source and the idea of a blazing fire. On this theory, other means of fire-production can be regarded as being developed at a much later period, either from observation of natural events or as a by-product of chipping and grinding processes in toolmaking industries.

There can be no direct evidence for any theory of the origin of the use of fire, but it seems not unreasonable to regard the awe-inspiring character of natural fires and the rarity of small-scale fire production in Nature as militating against acceptance of present theories. In contrast, heat or flame produced by the method here suggested would be, at most, only mildly startling, while the care accorded by some primitive races to their existing fires could be interpreted as deriving from a period when an active compost heap was a most precious family possession. The 'compost heap' theory would also allow for widespread discovery of the use of fire by early man, even in regions where natural sources of fire were not available.

PSYCHOLOGY

Validity of Prediction based on Cross-Sectional Analysis

CROSS-SECTIONAL analysis, by means of which is investigated the behaviour of a cross-section of the population at a given point in time, is a convenient method in many fields of research where age or maturational differences are of interest. Implicit in the findings of such investigations are predictions about the future behaviour of the groups concerned. Such predictions are, however, based on the assumption that the behavioural differences between groups are due to the age differences involved, and that future age changes will bring about similar behavioural differences. The fallibility of such predictions in the field of demography has been pointed out[1]. This investigation is aimed at checking similar findings in the field of absence behaviour in an industrial situation.

The absence records of a group of 140 continuous service men engaged on manual work in an engineering firm during the period 1949–58 formed the material of the investigation. The sample was divided into four age-groups, each covering an approximate 10-yr. span, so that the median age of one group at the end of the period was approximately equal to that of the next oldest group at the beginning of the period. The records for each group were first analysed cross-sectionally for a 2-yr. period 1949–50, and the same groups were then followed longitudinally for a further 8 years. Two measures of absence were used in the analysis: (*a*) the number of occasions of absence, and (*b*) the average length of absences. The data were divided into five 2-yr. periods. The results for the first and last of these periods are summarized in Tables 1 and 2.

For the length of certified sickness absence (Table 2), the cross-sectional analysis based on the 1949–50 data shows a sharp increase in the length of absence for the oldest group. This agrees with the findings of previous investigators, for example, ref. 2. The prediction from this finding would be that, as age increased, group 3 would show a similar increase in length of sickness absence, and an examination of the

Table 1. FREQUENCY OF ABSENCE FOR REASONS OTHER THAN SICKNESS

Age group	No in group	Median age at 1/1/49	1949–50 Average No of absences per man	1949–50 No and percentage of men with 0 absences	1957–58 Average No of absences per man	1957–58 No and percentage of men with 0 absences
1	20	23	2·35	3 (15)	2·75	3 (15)
2	51	31	1·61	16 (31)	1·71	18 (35)
3	34	40	1·18	18 (53)	1·71	14 (41)
4	35	51	1·63	15 (43)	1·49	15 (43)
All groups	140	35	1·61	52 (37)	1·8	50 (36)

Table 2. LENGTH OF CERTIFIED SICKNESS ABSENCES

Age group	No in group	Median age at 1/1/49	1949–50 Average length of absence (days)	1949–50 Percentage of absences lasting more than 2 weeks	1957–58 Average length of absence (days)	1957–58 Percentage of absences lasting more than 2 weeks
1	20	23	7·43	14	3·83	0
2	51	31	7·65	18	7·47	13
3	34	40	7·82	18	13·12	53
4	35	51	14·22	67	12·64	55
All groups	140	35	9·9	34	10·9	41

data for the end of the period (1957–58) shows that such an increase has, in fact, occurred. In this case the longitudinal method supports the findings of the cross-sectional method, making it probable that this is a true ageing effect.

In the case of frequency of absence (Table 1) this is not so. The cross-sectional analysis (1949–50) shows the youngest group to have a frequency of absence for reasons other than sickness higher than the other groups. Similar findings by other investigators are reported[3]. On this basis one would expect their absences to become less frequent as they grew older, but the data for the end of the period show that this has not happened and that their absence frequency has, in fact, increased relative to the average. The higher absence frequency of this group seems to be a continuing characteristic, independent of age.

The conflict of evidence arising from the use of these two methods indicates the need for greater caution in the interpretation of the results of cross-sectional investigations. The differences shown by this method may be due to the age differences involved, but the possibility that other factors are operating must also be borne in mind.

This work will be published in greater detail in *Occupational Psychology*.

Role of Experience in Misreaching produced by Visual Cortex Lesions

WHEN the macular projection area—that part of the visual striate cortex to which the macular region of the retina projects—is removed in monkeys a characteristic symptom can be demonstrated. The animal frequently misreaches for small pieces of food when they are presented to him on a flat surface[1,2]. The error involved may be as much as three inches, and two inches is common. It is the direction of the object, rather than the distance, which is usually gauged incorrectly by the animal, that is, his fingers fall to the sides of the object rather than beyond or in front of it. The direction of the error appears to depend primarily on which hand is used, misreaching to the left tending to occur when the left hand is used and misreaching to the right when the right hand is used. The position of the food relative to the animal's body is also important. This type of behaviour is often called 'past-pointing', but since the error tends to be one of direction rather than distance, and also because past-pointing is also used to refer to vestibular or cerebellar derangement, we prefer to use the term 'misreaching'.

Misreaching is easily demonstrated during the first few days after operation. It declines, and almost invariably disappears within ten days. Afterwards, operated animals are as adept as normal animals at detecting and picking up small objects.

It has never been shown whether practice is necessary for this recovery to occur or whether it is the result of a spontaneous re-organization of the visual system after part of it has been damaged. The latter hypothesis might seem rather improbable were it not for the fact that we now know that the rhesus monkey is not blind in the centre of its visual field after this operation, although this region is less efficient than in the normal animal[3]. Whichever hypothesis is correct, it is interesting to contrast the high degree of plasticity in such monkeys with the lack of correction in orientation after eye rotation or similar alterations in Amphibia[4].

In order to distinguish between these two views about the recovery process—spontaneous recovery or practice—an animal was kept in total darkness for ten days after the macular projection area had been removed; he was then tested for misreaching. The result was clear. The animal misreached in exactly the same manner and for the same length of time as previous animals which had been tested without a delay after surgery. A control animal which was kept in the dark for 10 days showed no misreaching when it emerged. These statements are based on daily observations made in an experimental situation which permits quantitative estimates of misreaching from ciné film records.

It is concluded that, although the cause of misreaching is still not perfectly clear, recovery depends on experience in the light. It cannot be said without further experimental work whether mere exposure to the light is sufficient, or whether specific practice in reaching for objects is necessary. The latter appears more likely in view of recent work on the recovery of misreaching by human subjects wearing prisms[5].

This investigation was supported by the U.S. Air Force under Contract *AF* 61 (052)–185. One of us (A. C.) held a Medical Research Council fellowship while doing this work.

MATHEMATICS

Equation of Motion in Five Space

THERE exist many models for the description of the gravitational and electromagnetic field Perhaps the most successful formalism developed is still that of Kaluza[1], with notable improvements by Bergmann[2] since it reproduces exactly the classic equations of the electromagnetic field with gravity However, there still remained the well-known difficulties associated with the classic treatment of Nature so that generalizations which lead to substantially different equations were made in the hope that there could be included within the new frameworks an adequate theory encompassing quantum-phenomena as well These hopes have not been realized; but nevertheless it is most difficult to relinquish a theory which by and large has been subject to confirmation—quite strikingly in recent times using techniques based on the Mossbauer effect[3] In addition to numerous verifications of the original version of the theory, Einstein, Infeld and Hoffmann[4] have shown that there exists a most æsthetic feature, namely, that the field equations themselves determine the classic equations of motion of 'singularities' or 'particles' in the field Thus it is not necessary to supplement the field equations with ponderomotive equations.

It seems to be of some interest to investigate the equations of motion in a five-dimensional setting to examine departures from the usual results. I will assume that the additional dimension is space-like and take for the field equations

$$R_{\mu\nu} - g_{\mu\nu}R/2 = 0 \qquad (1)$$
$$\mu,\nu = 0, 1, 2, 3, 4$$

where $g_{\mu\nu}$ is the metric tensor, $R_{\mu\nu}$ the Riemann-Christoffel curvature tensor and R its contraction '0' indices will be considered temporal, the others spatial with the '4' index reserved for the additional dimension Now if we seek approximate solutions of the field equations corresponding as closely as possible to the four-dimensional case it is found on reckoning differentiation with respect to X_4 as leading to quantities of the same order of smallness as differentiation with respect to $X_0(= ct)$, and then proceeding in much the same fashion as in reference 2 and 4 'co-ordinates' of the 'particles' will involve X_4 as well as X_0, which would imply that the equations of motion for the position of the 'particles' will be partial differential equations rather than total differential equations In addition to a field, which, in view of the Kaluza theory, may be interpreted as that arising from a charged 'particle,' there arises another which I make no attempt to interpret here

For purposes of comparison let us record the results of the calculations for the metric tensors to that order essential to obtain the Newtonian approximation These are

$$g_{00} = 1 - c^{-2} \sum_j((12\varkappa M_j + 6\varkappa P_j)/13) V_j$$

$$g_{0s} = (6\varkappa/13)c^{-3} \sum_j(3M_j \partial\xi_j^s/\partial t - (13/2\varkappa)^{1/2}(cQ_j)\partial\xi_j^s/\partial X^4) V_j$$

$$g_{4s} = (6\varkappa/13)c^{-3} \sum_j((13/2\varkappa)^{1/2}Q_j\partial\xi_j^s/\partial t - 3P_jc\partial\xi_j^s/\partial X^4) V_j \qquad (2)$$

$$g_{40} = - 6c^{-2}(\varkappa/26)^{1/2} \sum_j Q_j V_j$$

$$s = 1, 2, 3$$

where

$$V_j = ((X^s - \xi_j^s)(X^s - \xi_j^s))^{-1/2} \qquad (3)$$

ξ_j^s, the sth co-ordinate of the jth 'particle,' and M_j and Q_j its mass (gm) and charge (E S U) respectively. P_j may be considered another parameter describing another property of the jth particle It is to be noted that $\varkappa$ is Newton's constant of gravity and that the dimensions of the P_j is that of $(\varkappa)^{-1/2}$ times charge (E S.U) M_j, Q_j and P_j could be functions of $X_0(= ct)$ and X_4 satisfying

$$\begin{aligned}\partial M_j/\partial t - (13/18\varkappa)^{1/2}c\partial Q_j/\partial X^4 &= 0\\ \partial Q_j/\partial t - (18\varkappa/13)^{1/2}c\partial P_j/\partial X^4 &= 0\end{aligned} \qquad (4)$$

while the partial differential equations of motion for the jth particle in the Newtonian approximation turn out to be·

$$\partial^2\xi_j^s/\partial t^2 - (1/3)(cQ_j/M_j)(26/\varkappa)^{1/2}\partial^2\xi_j^s/\partial X^4\partial t + (P_jc^2/M_j)\partial^2\xi_j^s/\partial X^{42} \qquad (5)$$
$$- \sum_{i\neq j} (\varkappa M_i + Q_iQ_j/M_j - 4\varkappa P_jM_i/(13M_j) + \varkappa P_iP_j/M_j - 4\varkappa P_i/13)\partial V(i,j)/\partial\xi_j^s = 0$$

where

$$V(i,j) = ((\xi_i^s - \xi_j^s)(\xi_i^s - \xi_j^s))^{-1/2} \qquad (6)$$

with the time t in seconds units and X^4 the additional co-ordinates expressed in cm units

It is to be noted that even for an isolated 'particle' or systems of particles' far removed from one another the co-ordinates ξ_j^s satisfy the second-order equation obtained by considering only the first three terms of equation 5 which may be expressed as.

$$(\partial/\partial t - c_{j+}\partial/\partial X^4)(\partial/\partial t - c_{j-}\partial/\partial X^4)\ \xi_j^s = 0 \qquad (7)$$

if M_j, Q_j. and P_j are presumed constant. In equation 7 c_{j+} is given by

$$c_{j\pm} = (Q_j/M_j)(18\varkappa/13)^{-1/2} \pm ((Q_j/M_j)^2(18\varkappa/13)^{-1} - P_j/M_j)^{1/2})c \qquad (8)$$

which implies with the f_j^s and g_j^s arbitrary functions of the indicated arguments that

$$\xi_j^s = f_j^s(c_{j+}t + X^4) + g_j^s(c_{j-}t + X^4) \qquad (9)$$

a wave motion for the ξ_j^s which is propagated with velocities $- c_{j+}$ in our $t - X^4$ space

The insistence that equation 7 be a hyperbolic partial differential equation has as consequence $P_j/M_j < 0$ to assure this property even when $Q_j = 0$ For an electron the velocity of propagation attains a value of the order 10^{21} times the velocity of light One would be forced to conclude that if it were possible to communicate in such a space it would be a relatively simple task to assess the state of the far reaches of the universe within a considerably shorter interval of time than heretofore and so indeed to consider occurrences almost anywhere to be of a contemporary nature In any event the structure of the equations of motion which have emerged even for 'free particles' may perhaps provide us with other conceptual possibilities the starting point of which may lead to a theory with less startling consequences

CHRISTOPHER GREGORY

University of Hawaii,
Honolulu.

FORTHCOMING EVENTS

Tuesday, January 2

Royal Geographical Society (joint meeting with the Geographical Association and the Institute of British Geographers, at 1 Kensington Gore, London, S W 7), at 3 p m —Prof David Linton "Some Contrasts in Landscapes in the F I D S Sector of the Antarctic"

Wednesday, January 3

British Institution of Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 10 a m —All-day Symposium on "Data Transmission"

Institution of Mechanical Engineers, Lubrication and Wear Group (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Discussion on "Wear of Rubbing Electrical Contacts"

Wednesday, January 3—Friday, January 5

Science Masters' Association (at Imperial College, London, S W 7), at 10 a m daily—Annual Meeting

Thursday, January 4

Institute of Refrigeration (at the Institute of Marine Engineers, The Memorial Building, 76 Mark Lane, London, E C 3), at 5 30 p m —Mr S I Neuman "Refrigeration in Dam Cooling"

Institution of Electrical Engineers (at Savoy Place, London, W C 2), at 5 30 p m —Mr F J Lane "The Transmission of Power at High Voltages" (Fourth Hunter Memorial Lecture)

Royal Society of Medicine, Neurology Section (at 1 Wimpole Street, London, W 1), at 8 p m —Meeting on "Inborn Errors of Metabolism" Speakers Dr Richard H Dobbs, Dr L I Woolf and Dr G A Rose

Friday, January 5

Plastics Institute (at the Institution of Electrical Engineers, Savoy Place, London, W C 2), at 2 30 p m —Prof M Stacey, F R S "Nature's Plastics" (Annual Young People's Lecture)

Society of Chemical Industry, Fine Chemicals Group (at 14 Belgrave Square, London, S W 1), at 6 30 p m —Mr F P Doyle "Recent Advances in the Chemistry of Penicillin"

Institution of Electrical Engineers, Medical Electronics Discussion Group (at Savoy Place, London, W C 2), at 6 p m —Discussion on "Membranes" opened by Dr H Davson

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Biochemist for the Wellcome Laboratory, situated at the Veterinary Hospital—The Secretary of University Court, The University, Glasgow, W 2 (January 12)

Ornithologist (with a good honours degree and/or high professional attainment in ornithology) at London Headquarters, for work on ornithological matters at National level—The Nature Conservancy (E), 19 Belgrave Square, London, S W 1 (January 12)

Lecturer (with an honours degree or equivalent qualifications, and preferably special interests and experience in general psychology, experimental psychology or statistics) in the School of Applied Psychology—The Agent-General for New South Wales, 56–57 Strand, London, W C 2, and the Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia (January 15)

University Lecturer (with an honours degree in agriculture, or in agricultural science, together with experience in teaching and research, and preferably with interests in the field of animal husbandry) in Agriculture—The Secretary of the Appointments Committee of the Faculty of Agriculture, The University, Cambridge (January 16)

Research Fellow or Research Assistant in Physics at the University of New England, to assist in a programme of research into the physics of ice, water and clouds—The Registrar, University of New England, Armidale, New South Wales, Australia, and The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, January 19)

Lecturer in Geography—The Registrar and Secretary, The University, 38 North Bailey, Durham (January 20)

Lecturer in Physics—The Registrar and Secretary, The University, 38 North Bailey, Durham (January 20)

Lecturer (preferably with a major interest in applied mechanics, especially theory of machines, stress analysis and properties of materials, or applied thermodynamics) in Engineering (Mechanical) —The Registrar, The University, Manchester 13 (January 20).

Lecturers (2) (suitably qualified honours graduates) in Geography in the Liberal and Social Studies Department, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana—The Assistant Registrar, Kwame Nkrumah University of Science and Technology, 29 Tavistock Square, London, W C 1 (January 20)

Scientific Officer (with a first- or second-class honours degree in mathematics with statistics, or a Diploma in Statistics) in the Statistics Section, for duties mainly concerned with the design and analysis of field and laboratory experiments—The Secretary, The Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen (January 20)

Associate Professor in Concrete Technology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, January 24)

Lecturer or Assistant Lecturer in the Sub-department of Computation—The Secretary and Registrar, The University, Southampton (January 26)

Demonstrators (graduates with some research experience) in the Department of Organic Chemistry—The Registrar, The University, Liverpool, quoting Ref CV/575/N (January 31)

Demonstrators (2) (with a science degree with a major in zoology) in Zoology at the University of Melbourne, Australia—The Registrar, University of Melbourne, Parkville, N 2, Victoria, Australia (January 31)

Imperial Chemical Industries Research Fellows (one or more) —The Secretary, The University, Aberdeen (January 31)

Lecturer in Civil Engineering—The Registrar, The University, Sheffield (January 31)

Lecturer in Mechanical Engineering at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Hong Kong and London, January 31)

Senior Lecturer in Inorganic Chemistry at the University of Natal, Durban—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (South Africa and London, January 31)

Professor of Botany, and a Professor of Zoology—The Secretary, University College, Galway, Republic of Ireland (February 5)

Imperial Chemical Industries Research Fellows in the various branches of Chemistry, Chemical Engineering, Engineering, Technology, Physics and allied subjects—The Registrar, The University, Manchester 13 (February 14)

Turner and Newall Research Fellows in Engineering, Inorganic Chemistry, Physics and allied subjects—The Registrar, The University, Manchester 13 (February 14)

Reader in Mathematics, and a Lecturer/Senior Lecturer in Mathematics at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, February 17)

Lecturers (2) in Fuel Technology and Chemical Engineering —The Registrar, The University, Sheffield (February 28)

Senior Lecturer in Electrical Engineering, and Lecturers (2) in Electrical Engineering at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, March 1)

Lecturers, Assistant Professors or Associate Professors in the Department of Mathematics (either at the Edmonton campus or the Calgary campus)—Prof M Wyman, Mathematics Department, University of Alberta, Edmonton, Alberta, Canada

Postdoctoral Assistant for the operation of a research mass-spectrometer for the detection of unstable reaction intermediates—J W Linnett, Inorganic Chemistry Laboratory, The University, Oxford

Research Assistant (science graduate), to work with tissue culture in relation to carcinogenesis—Prof H N Green, Department of Experimental Pathology and Cancer Research, School of Medicine, The University, Leeds 2

Scientific Officer or Senior Scientific Officer (with an honours degree and experience in microbiology) in the Bacteriology Department, for work on problems involving hygiene and the isolation and classification of micro-organisms—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, quoting Ref 61/17

Senior Histological Technician to take charge of a Research Laboratory—Chief Technician, Department of Morbid Anatomy, Institute of Orthopædics, 234 Great Portland Street, London, W 1
